mothers in these same years, thus tending to keep the ratio more constant. To the biologist this would seem to indicate that in the population of the United States, at least, there has been no significant impairment of innate reproductive capacity in recent years, if ever, nor any serious alteration of average parity performance among the women in the population who actually reproduced at all.

In general, Pearl's analysis of the factors influencing reproductivity seems to confirm those who believe that the rapidly falling birth rate is a reflection of social, economic and other extraneous factors rather than an innate biologic phenomenon.

Current Comment

SUPREME COURT ACTS ON APPEAL FROM PROCTOR DECISION

On October 23 the Supreme Court of the United States indicated that it would not now pass on the suit brought by the Department of Justice charging the American Medical Association, through various officials and also some physicians and hospitals of the District of Columbia, as well as other medical societies, with conspiracy to violate the Sherman antitrust law by activities against Group Health Association, Inc., of Washington, D. C. The Department of Justice had appealed directly to the Supreme Court from the decision rendered by Justice Proctor of the District Court for the District of Columbia. Attorneys for the American Medical Association did not oppose this attempt by the Department of Justice.

Commenting on the decision, the *Washington Post* said:

A PROPER SETBACK

At some future date the Supreme Court may find it desirable to review the government's anti-trust case against the American Medical Association and the District Medical Society. The Department of Justice appears determined to fight Judge Proctor's decision to the last ditch. And the medical profession would certainly carry the dispute to the Supreme Court if the Proctor opinion should be overruled in the Court of Appeals.

For the present, however, the Supreme Court has quite properly declined to review the case. It sees no reason for departure from the customary judicial procedure. No constitutional issue is involved in the charges against the medical association.

The case turns merely upon interpretation of the anti-trust laws. The Department of Justice is attempting to stretch the Sherman act to provide protection for the Group Health Association against alleged restraints on the part of the organized medical profession.

Should the Supreme Court set a precedent of accepting appeals directly from the federal district courts, where no constitutional issue is involved, it would soon be overburdened with litigation. The statute giving constitutional cases a right of way to the highest tribunal makes it all the more important for the court to maintain a rigid check on other petitions for review of less vital or complicated issues.

There are many indications that the Anti-Trust Division has been unduly excited over the idea of prosecuting the medical association for alleged restraint of trade. In effect,

the Supreme Court has sustained this criticism. It found nothing in the Anti-Trust Division's petition to justify singling out this case for special attention. If the division insists upon clinging to its strained interpretation of the anti-trust laws, it will at least have to rely upon the customary procedure for final judicial clarification.

A TESTIMONIAL TO EVARTS GRAHAM

As indicated in our news columns, Dr. Evarts Ambrose Graham, Bixby professor of surgery at Washington University School of Medicine, St. Louis, was recently honored by the creation of a lectureship in his name. His contributions to the knowledge of physiology and surgery through his work on the pleura, the lung and the biliary tract are among the noteworthy contributions of the last twenty years. Moreover, his influence, through the accomplishments of his students, is worldwide. The announcement of the establishment of a Graham Lectureship to be given annually in St. Louis is a suitable recognition of his interest in education. Through this event Dr. Graham's influence in the advancement of scientific surgery will be prolonged.

POLIOMYELITIS IN THE EASTERN COTTON RAT

Successful transmission of the Lansing strain of poliomyelitis virus to the eastern cotton rat has been recently reported by Armstrong¹ from the National Institute of Health. The strain has been carried in series through seven cotton rat transfers, and animals of the eighth transfer had begun to develop symptoms at the time of reporting. Paralysis of the flaccid type developed in all. This animal is not vicious, multiplies readily in captivity, and in view of the probable interference with the importation of monkeys during the war may prove invaluable in continuing experimental investigations on infantile paralysis.

Association News

MEDICINE IN THE NEWS

The seventh season of broadcasting by the American Medical Association over the facilities of the National Broadcasting Company and affiliated stations opens Thursday November 2 at 4:30 p. m. eastern standard time (3:30 central standard time, 2:30 mountain time and 1:30 Pacific time). The title of the program will be Medicine in the News.

True to their title, the programs will consist of dramatizations based on what is happening in the world of medicine. Each program will include a principal news item from THE JOURNAL or some other reputable medical source or from *Hygeia*. This will be followed by one or more high lights on current medical news. Each program will close with a question of the week drawn from the question and answer correspondence of *Hygeia*. A question will be asked each week and answered the following week.

Since the program will be based on events as they proceed, it will be impossible to announce program topics in advance. Each program will be developed within the week immediately preceding its appearance and in part, perhaps, the programs will often be developed within forty-eight hours of their broadcasting.

1. Armstrong, Charles; The Experimental Transmission of Poliomyelitis to the Eastern Cotton Rat, *Sigmodon Hispidus Hispidus*, Pub. Health Rep. 54: 1719 (Sept. 22) 1939.

As heretofore, this is a sustaining program made possible through the cooperation of the National Broadcasting Company. A sustaining program brings no revenue to any radio station or to the network. Therefore radio stations, except those owned and operated by the National Broadcasting Company, are not obligated to broadcast the program. State and county medical societies should express interest in the program by letter or personal interview with the manager of the local radio station. Such evidence of local interest may be the deciding factor in broadcasting the program locally.

Following is a list of the radio stations affiliated with the Blue network of the National Broadcasting Company. This is a list of stations to which the program is available, not a list of stations which are certain to broadcast the program. A list of stations announcing intention to broadcast the program will be published in a later issue of THE JOURNAL.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Funds for Cancer Research.—The University of California has received \$27,166 in gifts for cancer research by Ernest O. Lawrence, Ph.D., professor of physics and director of the radiation laboratory, it was announced October 5. The U. S. Public Health Service gave \$23,000 for cancer work under the provisions of the National Cancer Institute Act and the Rockefeller Foundation gave \$4,166. Other donations included \$5,000 by the General Education Board, New York, for the Institute of Child Welfare; \$3,000 for research on sylvatic plague at the Hooper Foundation by the Rosenberg Foundation; \$900 to the Institute of Child Welfare by the Josiah Macy Jr. Foundation, and \$3,750 for research by Dr. Herbert M. Evans on hormones, by the Rockefeller Foundation.

Southern California Medical Association.—The one hundred and first semiannual convention of the Southern California Medical Association will be held at the Samarkand Hotel, Santa Barbara, November 3-4. The guest speakers will be Drs. William Edward Chamberlain, professor of radiology and roentgenology, Temple University School of Medicine, Philadelphia, and Frank J. Heck, hematologist at the Mayo Clinic, Rochester, Minn. They will discuss respectively "Pitfalls in X-Ray Diagnosis" and "Treatment of Pernicious Anemia and the Iron Deficiency Anemias." Other speakers will include:

- Dr. Harold E. Crowe, Los Angeles, Short Hospitalization for Fractures.
- Dr. Ralph V. Byrne, Los Angeles, Surgical Concepts of Hyperthyroidism.
- Dr. James Norman O'Neil, Los Angeles, Intraperitoneal Rupture of the Urinary Bladder as Encountered by the General Surgeon.
- Dr. Pierre P. Viole, Los Angeles, Use of Human Convalescent Scarlet Fever Serum in Streptococcal Infection of the Ear, Nose and Throat.
- Dr. Louis E. Martin, Los Angeles, Serum Therapy versus Sulfapyridine Therapy in Pneumonia.
- Dr. William P. Thompson, Los Angeles, The Apparent Benignity of Rheumatic Fever in Southern California.
- Dr. Maurice P. Foley, Los Angeles, Present Day Concepts in the Treatment of Liver Disease.
- Dr. Charles H. Pettet, Los Angeles, Acute Abdominal Pain in Childhood.

There will be a symposium on hematology and one on intestinal obstruction.

DELAWARE

Society News.—Dr. Kenneth M. Corrin discussed the incidence of syphilis before the New Castle County Medical Society in Wilmington October 17. Dr. Norman L. Cutler showed a moving picture on ophthalmology and Drs. Oscar N. Stern and Junius A. Giles Jr. presented a case of placenta praevia.

State Hospital Observes Anniversary.—The Delaware State Hospital celebrated its fiftieth anniversary and dedicated its new chapel September 28. Included among the speakers was Dr. Edward A. Strecker, professor of psychiatry, University of Pennsylvania School of Medicine, Philadelphia, whose address was entitled "Social Implications of Psychiatry."

IDAHO

State Medical Election.—Dr. Abram M. Newton, Pocatello, was chosen president-elect of the Idaho State Medical Association at the annual meeting in Boise August 23-26. Dr. Fern M. Cole, Caldwell, was installed as president and Dr. Joseph N. Davis, Twin Falls, was elected secretary. The 1940 meeting will be held at Sun Valley.

ILLINOIS

Society News.—Dr. Samuel J. Fogelson, Chicago, addressed the Effingham County Medical Society, Effingham, October 10 on "Treatment of Gastrointestinal Ulcerative Disease Based on Modern Physiology."—The Kankakee County Medical Society was addressed October 12 by Dr. Howard A. Lindberg, Chicago, on the treatment of pneumonia.—At a meeting of the Fulton County Medical Society in Canton October 12 Dr. Leroy H. Sloan, Chicago, discussed "Neurology for the General Practitioner."—Dr. Paul H. Wosika, Chicago, addressed the Will-Grundy County Medical Society in Joliet October 6 on "Auricular Fibrillation."—At a joint meeting of the Rock Island medical and dental societies, Rock Island, October 10

Dr. Frederick B. Moorehead, Chicago, discussed "Use of Elastic Traction in the Management of Jaw Fractures and in Plastic Surgery."—Dr. Frank Deneen, Bloomington, spoke before the Madison County Medical Society in Alton October 6 on "Medical Management of Gallbladder Disease."—At a meeting of the Sangamon County Medical Society in Springfield October 5 Dr. Irvine H. Page, Indianapolis, discussed hypertension.—A symposium on medical economics was presented before the Champaign County Medical Society October 12 by Drs. Edwin S. Hamilton, Kankakee; Harold M. Camp, Monmouth, and Calvin C. Applegate, U. S. Public Health Service, Chicago.

CHICAGO

Special Lectures.—Dr. Harry Gideon Wells, professor and chairman of the department of pathology, School of Medicine of the Division of Biological Sciences, University of Chicago, will deliver the fourth Christian Fenger Lecture of the Institute of Medicine of Chicago and the Chicago Pathological Society at the Palmer House November 13. He will discuss "A Neglected Subject, Adipose Tissue." Birdsall Holly Broadbent, D.D.S., director of the Bolton Foundation, Western Reserve University, Cleveland, will present the fourth Frank Billings Lecture of the Thomas Lewis Gilmer Foundation at the Palmer House November 24. The title of the lecture will be "Clinical Significance and a Roentgenographic Method of Measurement of Disturbances in Facial Growth."

Dr. Whitecotton Comes to University of Chicago Clinics.—Dr. George Otis Whitecotton, superintendent of the Stanford University Hospitals, San Francisco, for the last four years, has been appointed to the same position with the University of Chicago Clinics. Dr. Arthur C. Bachmeyer, director of the clinics and associate dean of the Division of Biological Sciences, has been acting as superintendent in addition to his other duties since the resignation of John C. Dinsmore in 1934. Dr. Whitecotton will manage Billings Hospital, Bobs Roberts Memorial Hospital for Children and the Max Epstein Clinic, while the supervision of Lying-In Hospital and the Home for Destitute Crippled Children will continue under other assistants to Dr. Bachmeyer. Dr. Whitecotton graduated at the Stanford University School of Medicine in 1933.

IOWA

Fracture Clinic.—The Iowa State Medical Society will hold a fracture clinic at the Hotel Fort Des Moines, Des Moines, November 8. The morning will be given over to the presentation of cases while the afternoon will be devoted to papers by visiting speakers.

Pneumococcus Study Course.—The state department of health will conduct a pneumococcus study course at the state hygienic laboratory, Iowa City, October 31-November 2. The course is intended primarily for laboratory workers and attending physicians associated with pneumonia typing stations. Funds assigned to the department through the U. S. Public Health Service make it possible to reimburse the registrants for most of the travel and other expenses incident to the course.

Campaign Against Smallpox.—A statewide program against smallpox is under way in Iowa with the cooperation of the committee on child health and protection of the Iowa State Medical Society, the state department of health, county medical societies and lay organizations, according to the *Journal of the Iowa State Medical Society*. At the 1939 session of the state society approval was given to such a campaign on the recommendation of the committee on child health and protection. The actual administration of the vaccine will take place October 30-November 11. About seventy-five of the county medical societies in the state have appointed committees to take charge of the work in their communities, and many of the societies have taken paid advertising in the local newspapers. According to the journal, Iowa for many years has ranked well at the top of the states with the highest rates, the climax being reached in 1938 when 1,170 cases of smallpox were recorded.

MICHIGAN

Course in Diagnostic Roentgenology.—The University of Michigan Medical School, Ann Arbor, announces a post-graduate course in diagnostic roentgenology October 30-November 4. Topics to be considered include the diagnosis of lesions of the lungs and pleura, examination of the heart and great vessels, and diagnosis of diseases of the chest wall, and soft tissues of the neck and mediastinal structures. Conducting the course will be Drs. Fred J. Hodges, professor of roentgenology; Vincent C. Johnson and Isadore Lampe, assistant professors, and Hobart H. Wright, instructor.

MINNESOTA

Public Health Association Meeting.—The thirty-third annual session of the Minnesota Public Health Association will be held at the Nicollet Hotel, Minneapolis, November 3, with the Hennepin County Tuberculosis Association acting as host. At the annual Christmas Seal dinner, Dr. James D. Adamson, professor of medicine at the University of Manitoba Faculty of Medicine, Winnipeg, medical director of St. Boniface Sanatorium, St. Vital, Man., and consultant in pulmonary diseases, department of pensions and national health of Canada, will speak on "War and Tuberculosis As We See It in Canada." Dr. Sidney A. Slater, Worthington, president of the Minnesota Public Health Association, will give a memorial address honoring the late Dr. Charles H. Mayo, Rochester, a former president and later honorary president of the Minnesota Public Health Association. Gov. Harold Stassen will speak and greetings will be extended by Dr. Stephen H. Baxter, Minneapolis, president of the Hennepin County Tuberculosis Association. Dr. Frank J. Hirschboeck, Duluth, a member of the state heart committee, is to be toastmaster. Distinguished Service Christmas Seal Awards for 1938 will be presented.

MISSOURI

The Evarts Graham Lectureship.—The twentieth anniversary of Dr. Evarts A. Graham as Bixby professor of surgery at Washington University School of Medicine, St. Louis, was observed with two days of scientific sessions October 11-12. At a dinner, which concluded the celebration, the establishment of the Graham Lectureship was announced. It is hoped that the first of these lectures, which will be given annually, will be delivered in the spring. About forty-five former pupils of Dr. Graham gathered from all parts of the country to attend the meeting. One representative came from Australia and others were prevented from coming by the outbreak of war. A graduate of Rush Medical College, Chicago, class of 1907, Dr. Graham has during his career been given many honors including the Leonard prize of the American Roentgen Ray Society in 1925; a gold medal of the Radiological Society of North America in 1925; a gold medal and certificate of merit of the St. Louis Medical Society in 1927, and a gold medal of the Southern Medical Association in 1933. He was chairman of the Section on General and Abdominal Surgery of the American Medical Association in 1925, president of the St. Louis Surgical Society in 1925 and of the American Association of Thoracic Surgeons in 1928. He has been co-editor of the *Archives of Surgery* since 1920; editor of the *Journal of Thoracic Surgery* since 1931 and is the author of "Empyema Thoracis" and "Diseases of the Gallbladder and Bile Ducts," as well as of many articles on his specialties.

NEW JERSEY

State Society's Clinical Conference.—The Medical Society of New Jersey will present its second Fall Clinical Conference November 9-10 in Jersey City with the Hudson County Medical Society as host. Fifteen hospitals will provide material for clinics in general surgery, general medicine, pediatrics, industrial and traumatic surgery, neurosurgery, bronchoscopy and chest surgery, obstetrics, urology and psychiatry. Clinics will be held in the afternoons at the Jersey City Medical Center. At a dinner at the Carteret Club Friday evening Dr. James F. Norton, Jersey City, will be toastmaster and Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will speak on "American Medicine and the National Government."

NEW YORK

Society News.—Dr. Konrad Birkhaug, Bergen, Norway, former associate professor of bacteriology, University of Rochester School of Medicine, addressed the Rochester Academy of Medicine October 4 on "The Use of Sulfanilamide in Experimental Tuberculosis."—Charles S. Baker, legal counsel for the Medical Society of the District of Columbia, Washington, D. C., addressed the Medical Society of the County of Monroe, Rochester, October 17 on health insurance.—Dr. George Draper, New York, addressed the Medical Society of the County of Westchester, White Plains, October 17 on "Observations from the Psychological Panel of Persons Who Develop Peptic Ulcer."

New York City

Faculty Changes at Cornell.—Joseph C. Hinsey, Ph.D., professor and head of the department of physiology at Cornell University Medical College, has been appointed professor and head of the department of anatomy to succeed the late Charles R. Stockard, Ph.D. During the present year he will also be

acting head of the department of physiology. William H. Chambers, Ph.D., has been promoted to the rank of associate professor of physiology and Kendrick Hare, Ph.D., to that of assistant professor of physiology. Dr. Hinsey took his doctorate at Washington University, St. Louis, in 1927. He was a member of the faculty of Northwestern University Medical School, Chicago, from 1927 to 1929, when he was appointed associate professor of anatomy at Stanford University School of Medicine, San Francisco. After a year he became professor at Stanford and remained there until his appointment to Cornell in 1936.

Society News.—Dr. Paul Reznikoff delivered a Friday afternoon lecture before the Medical Society of the County of Queens October 6 on "Blood Dyscrasias of Interest to the General Practitioner." Dr. James Alexander Miller spoke October 20 on "Early Diagnosis of Pulmonary Tuberculosis."—Speakers at the first fall meeting of the Medical Society of the County of Kings October 17 were Drs. Burrill B. Crohn, New York, on "Regional Ileitis: Medical Aspects, Surgical Indications"; Byrl R. Kirklin, Rochester, Minn., "Bleeding Lesions of the Intestinal Tract," and Charles W. Mayo, Rochester, Minn., "Carcinoma of the Duodenum, Jejunum and Ileum."—Dr. Benjamin R. Shore Jr. addressed the New York Surgical Society October 11 on "Carcinoma of the Breast."

OHIO

Professor Froehlich Comes to Cincinnati.—Dr. Alfred Froehlich, former professor of pharmacology, University of Vienna, has been appointed pharmacologist to the May Institute for Medical Research of the Jewish Hospital, Cincinnati. Dr. Froehlich is the discoverer of the syndrome that bears his name.

District Meeting in Cleveland.—The Fifth District of the Ohio State Medical Association held its annual meeting in Cleveland October 20. The guest speakers were Drs. Frederick Christopher, Evanston, Ill., on "Treatment of Wounds" and "Carcinoma of the Stomach," and Dr. Samuel A. Levine, Boston, on "Interpretation of a Systolic Murmur" and "Prognosis of Rheumatic Heart Disease."

Postgraduate Day.—The Summit County Medical Society is sponsoring its eighth postgraduate day at the Mayflower Hotel, Akron, November 8 with the following speakers: Drs. Wilber E. Post, professor of medicine, Rush Medical College; Charles B. Puestow, associate professor of surgery, University of Illinois College of Medicine, and George H. Gardner, assistant professor of gynecology, Northwestern University Medical School, all of Chicago.

OREGON

Society News.—Dr. Harold L. Blosser, Portland, addressed the Multnomah County Medical Society, Portland, October 4 on "Social and Economic Problems in Industrial Medicine."—Dr. Roger Anderson, Seattle, addressed the Polk-Yamhill-Marion Counties Medical Society October 10 on "Fractures of the Clavicle and Injuries in the Region of the Shoulder Joint" and on "Fractures of the Leg."—Dr. Conrad A. Loehner, Salem, addressed the Lane County Medical Society September 17 at Cottage Grove on "Barbiturates and Hypnotics."

PENNSYLVANIA

State Medical Election.—Dr. Francis F. Borzell, Philadelphia, was chosen president-elect of the Medical Society of the State of Pennsylvania at the annual meeting in Pittsburgh October 2-5, and Dr. Charles H. Henninger, Pittsburgh, was installed as president. Vice presidents elected were Drs. Charles G. Eicher, McKees Rocks; Ward O. Wilson, Clearfield; Walter J. Stein, Ardmore, and John J. Sweeney, Highland Park. Dr. Walter F. Donaldson, Pittsburgh, was reelected secretary. The 1940 session will be held in Philadelphia.

Philadelphia

Symposium on Pneumonia.—The Philadelphia County Medical Society held a meeting October 11 devoted to the subject pneumonia. Dr. Wheelan D. Sutliff, assistant director, pneumonia control division, bureau of laboratories, New York City Department of Health, spoke on "Application of Pneumococcus Bacteriology and Immunity to the Prevention and Cure of Pneumonia." Drs. John J. Shaw, state secretary of health, and Dale Cook Stahle of the health department staff, Harrisburg, discussed "Pneumonia—the Problem in Pennsylvania"; Charles L. Brown, etiology and diagnosis; Harrison F. Flippin, chemotherapy, and Henry A. Holle, U. S. Public Health Service, pneumonia as a national problem.

Pittsburgh

Annual Lecture on Diabetes.—The Renziehausen Memorial Lecture, established in 1937 for the advancement of knowledge of diabetes, will be delivered November 13 at Mellon Institute by Dr. Howard F. Root, Boston, on "Complications of Diabetes Mellitus."

Society News.—At a meeting of the Allegheny County Medical Society October 17 the speakers were Drs. John W. Stevenson on "Bicornate Uterus Associated with Pregnancy"; Joseph W. Hampsey, "Masking of Clinical Picture of Acute Mastoiditis During the Administration of Sulfanilamide," and Alfred B. Sigmund, Bridgeville, Pa., "Suppurative Appendicitis and Its Treatment with Alcohol."—Drs. John H. L. Heintzelman and James A. Cowan Jr. addressed the Pittsburgh Academy of Medicine October 10 on "Use of Ethyl Iodide in Chronic Nontuberculous Pulmonary Disorders" and "Delayed Flap in the Repair of Surface Defects" respectively.

WASHINGTON

State Medical Election.—Dr. Homer D. Dudley, Seattle, was named president-elect of the Washington State Medical Association at the annual meeting in August and Dr. Warren B. Penney, Tacoma, was installed as president. Dr. James G. Matthews, Spokane, was elected vice president and Dr. Vernon W. Spickard, Seattle, was reelected secretary. The 1940 meeting will be in Tacoma.

WISCONSIN

State Society Award to Dr. Johnson.—The State Medical Society of Wisconsin presented its fifteenth annual Council Award to Dr. Fred G. Johnson, Iron River, at the annual session in Milwaukee in September. In his citation Dr. Stephen E. Gavin, Fond du Lac, chairman of the council, observed that Dr. Johnson has been for thirty-nine years a family physician serving a scattered population over a large area. His services to medicine, as cited by Dr. Gavin, include having been twice president of a county medical society, president of the district medical society, nine years a counselor of the state society, seven years a preceptor of the University of Wisconsin Medical School and a collaborator in establishing and conducting the first tuberculosis sanatorium in Wisconsin. Dr. Johnson was born in 1872 and graduated from Rush Medical College, Chicago, in 1900.

HAWAII

New Director of Mental Hygiene.—Dr. Edwin E. McNiel, Honolulu, has been appointed director of the bureau of mental hygiene and in charge of the mental hygiene clinic under the board of health of Hawaii.

PHILIPPINE ISLANDS

Meeting at Canacao Hospital.—The U. S. Naval Hospital at Canacao entertained the senior class and the faculty of the University of the Philippines College of Medicine August 14. Papers were presented by Lieut. Alton C. Abernethy, Cavite, on "Lymphogranuloma Venereum" and Lieut. Comdr. Charles F. Flower, Cavite, "Fracture Dressings." Capt. Joseph J. A. McMullin and the hospital staff were hosts. Captain McMullin is assistant adjunct professor of surgery at the medical school in Manila.

GENERAL

Fellowships for Cancer Research Available.—The Finney-Howell Research Foundation, Inc., announces that all applications for fellowships for next year must be filed in the office of the foundation by Jan. 1, 1940. Applications received after that date cannot be considered for 1940 awards, which will be made the first of March. Fellowships carrying an annual stipend of \$2,000 are awarded for the period of one year with the possibility of renewal up to three years; when deemed wise by the board of directors, special grants of limited sums may be made to support the work carried on under a fellowship. Additional information may be obtained from the foundation, 1211 Cathedral Street, Baltimore.

Air Hygiene Meeting.—The fourth annual meeting of the Air Hygiene Foundation will be held at the Mellon Institute, Pittsburgh, November 14-15. Among features of the program will be a symposium on absenteeism in industry with Dr. Anthony J. Lanza, New York, presiding; a forum designed to show that "Industrial Health Pays Double Dividends"; reports on the foundation's engineering research at Harvard University by Philip Drinker, Ch.E., Boston; reports of medical research at Saranac Lake, N. Y., by Dr. Leroy U. Gardner,

and at the University of Pennsylvania by Drs. Eugene P. Pendergrass and Eliot R. Clark, Philadelphia. About 200 industrial firms are affiliated with the foundation.

Dermatologists to Meet in Philadelphia.—The second annual meeting of the American Academy of Dermatology and Syphilology will be held at the Bellevue-Stratford Hotel, Philadelphia, November 6-8. The sessions will consist of symposiums, courses lasting from one to four hours and round table discussions. Dr. Cornelius P. Rhoads, New York, will be the guest speaker Monday November 6 on "Vitamin B Complex." Tuesday will be devoted to clinical presentations at Jefferson Medical College of Philadelphia. There will be symposiums on syphilis, allergy, pharmaceutical therapeutics, physiology and chemistry of the skin. Dr. Paul A. O'Leary, Rochester, Minn., is president and Dr. Earl D. Osborne, Buffalo, secretary of the academy.

Special Society Election.—Dr. Frank R. Spencer, Boulder, Colo., was named president-elect of the American Academy of Ophthalmology and Otolaryngology at the annual session in Chicago October 8-13. Dr. Spencer will succeed Dr. Frank E. Brawley, Chicago, who becomes president January 1. Vice presidents elected were Drs. Arthur W. Proetz, St. Louis; Joseph F. Duane, Peoria, Ill., and Charles T. Porter, Boston. Dr. William P. Wherry, Omaha, was reelected executive secretary and Dr. Erling W. Hansen, Minneapolis, was made secretary for public relations, succeeding Dr. Ralph A. Fenton, Portland, Ore., resigned. The academy voted to sponsor a new venture in graduate medical education. Plans were made for the establishment of reading courses for hospital residents and interns planning to specialize in ophthalmology and otolaryngology.

Changes in Status of Licensure.—The California State Board of Medical Examiners reported the following actions taken at its regular meeting July 10-13:

Dr. Sharon M. Atkins, Los Angeles, license restored and placed on probation for five years.
Dr. Woodward B. Mayo, Burbank, Calif., certificate restored and placed on probation for five years.
Dr. Harold E. Morrison, Morro Bay, Calif., certificate restored.
Dr. Jesse C. Ross, Los Angeles, license restored.
Dr. Shunah Milton Mann, National City, Calif., license revoked July 13 following charges of "aiding and abetting" and of illegal operation.
Dr. Virgil J. McCombs, Los Angeles, license revoked following charges of alleged use of fictitious name and "aiding and abetting."
Dr. James T. Murray, Los Angeles, license revoked on charges of alleged narcotic addiction.
Dr. Walter M. Thorne, Fresno, Calif., license revoked on a charge of alleged narcotic addiction.
Dr. Donaciano Trevino, San Bernardino, Calif., license revoked following his conviction of violation of the Harrison Narcotic Act.
Dr. James Cushing Weld, Los Angeles, license revoked following charges of "aiding and abetting" and the use of a fictitious name.
Dr. Orel Alvin Welsh, Ventura, Calif., license revoked following his conviction on charges of performing an alleged illegal operation.

The New York State Board of Medical Examiners recently reported the following action:

Dr. Charles I. Gordon, formerly of Brooklyn, license revoked June 16.
The Virginia State Board of Medical Examiners announces the following:

Dr. J. Burton Nowlin, Lynchburg, Va., license reinstated June 21.

More Swindlers.—A man named George W. Remick, who often calls himself Dr. Remick, recently represented himself as a salesman for laboratory equipment firms and without authority has collected accounts owed to these firms. He has been traveling in California, Arizona, Texas, Colorado and New Mexico, posing as a salesman for the Jones Metabolism Equipment Company of Chicago and the Bristow Company of Los Angeles, among others. It is said that Remick approached a laboratory in El Paso, Texas, with the story that he had an option on some laboratory equipment which was being returned from China. Remick informed the laboratory physician that this apparatus was held by the customs office for fees which would have to be paid before it could be released and induced the doctor to give him a check to be paid to the customs office. Nothing further was heard from Remick and the customs office knew nothing of the occurrence. Remick is about 43 years old, about 5 feet 9 inches tall, weighs 190 pounds, has a fair complexion, light sandy hair with slight baldness and blue eyes. He is said to be talkative, late to appointments, fond of flashy clothes, usually with unmatched coat and trousers.—Further information has been furnished by the Chicago Better Business Bureau concerning a man who claimed to represent the "Hayes Company" of Indianapolis, reported in THE JOURNAL October 7, page 1423. The Indianapolis Better Business Bureau reported that several complaints had been received about this man, all from the Chicago area, and that no firm of Hayes and Company could be located in Indianapolis. The man appeared to be about 55 years old, 5 feet 8 inches tall and weighed about 140 pounds, it is reported. He claimed that he had bought

out a surgical supply house in Indianapolis for "almost nothing" and wanted to sell as much as possible so that he would not have to move much stock to Chicago, where he intended to start a business.

CANADA

Balfour Lecture at Toronto.—The fourteenth annual lecture under the Donald C. Balfour Lectureship in Surgery of the University of Toronto Faculty of Medicine, Toronto, was delivered October 11 by Prof. George Grey Turner, London, England, on "Transplantation of the Ureters."

Society News.—Dr. William E. Campbell, Winnipeg, was elected president of the Manitoba Medical Association at the annual meeting in September. Drs. Edward D. Hudson, Hamiota, and Hubert D. Kitchen, Winnipeg, were elected vice presidents and Dr. Clarence W. MacCharles, Winnipeg, secretary.

CORRECTION

Sigmund Freud's Age.—THE JOURNAL, October 14, page 1494, stated that Sigmund Freud died Sept. 22, 1939, in his eighty-third year. Dr. Freud was born May 6, 1856, and was therefore at the time of his death in his eighty-fourth year. Dr. Freud died about 3 a. m. September 23, London time, which would place his death before midnight New York time and, thus figured, would make the date of death there September 22.

Government Services

Increase in Salary for CCC Physicians

Since the receipt in this office of the item entitled, "Physicians Wanted for the CCC," published in THE JOURNAL, October 14, page 1500, the office of the surgeon of the Eighth Corps Area, Fort Sam Houston, Texas, has received instructions from the War Department to the effect that the salaries of all physicians on duty with the CCC would be \$3,200 per year instead of \$2,600 per year.

New Manager of Veterans Hospital

Dr. Grover C. Daniel, clinical director of the Veterans Administration Facility, Walla Walla, Wash., has been appointed manager effective October 1. He had been acting manager since the recent death of Dr. Orville D. Wescott, manager. Dr. Daniel was born in Olinville, Ky. He served in the army medical department from September 1917 until December 1918, and the following year graduated at Loyola University School of Medicine, Chicago.

Examinations for Government Positions

The U. S. Civil Service Commission announces open competitive examinations for the following positions: senior medical officer with a salary of \$4,600 a year; medical officer, \$3,800; associate medical officer, \$3,200. Applicants for the grade of senior medical officer must qualify in aviation medicine, cardiology or cancer research; for the other positions applicants may choose among fourteen optional branches. The registers resulting from these examinations will be used for filling vacancies in the U. S. Public Health Service, the Veterans' Administration, the Indian Service and the Civil Aeronautics Authority. Applicants must have graduated from recognized medical schools. Those applying for the position of senior medical officer must not have passed the fifty-third birthday; those for medical officer the forty-fifth and those for associate medical officer the fortieth. Dates for filing applications are as follows: November 13 if received from states other than those in the Far West as listed; November 16 if from Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming; March 11, 1940, if from points in Alaska south of the Arctic Circle; May 13, 1940, if from points in Alaska north of the Arctic Circle. Application forms may be obtained from the secretary of the Board of Civil Service Examiners at any first class post office, from the U. S. Civil Service Commission, Washington, D. C., or from the U. S. Civil Service district office in any of these cities: Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco, Honolulu, Balboa Heights, Canal Zone, and San Juan, Puerto Rico.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 30, 1939.

London Hospitals in Wartime

In previous letters it has been stated that, for the treatment of the numerous civilian casualties expected from air raids, London has been divided into ten sectors radiating from the center. The great hospitals are situated at the apexes of the sectors and become casualty clearing stations, while at the periphery, that is in the country, are the "base hospitals" to which the casualties will be evacuated for greater safety. The latter are hospitals or institutions which have been converted to this use. A description of the largest one, situated at some distance from London, illustrates typically the gigantic preparations which have been made. The hospital normally accommodated 2,200 mental patients, who were transferred to other institutions, but the malarial unit for the treatment of dementia paralytica was maintained, so that it would be available for the treatment of neurosyphilis. As the advanced base hospital for St. Thomas's and King's College hospitals it provides 2,560 beds. The big day room has been converted into three operating rooms, each with two tables, and there are smaller operating rooms elsewhere. Adjoining the operating rooms are resuscitation rooms, each with about twenty beds, for which a team has been trained. The former entertainment hall is a Red Cross dispensary.

For the treatment of the civilian casualties the hospital has been divided into five units, which to facilitate direction have been given different color schemes. Four of these units deal entirely with the care of the sick and wounded. Each is controlled by a surgeon on the staff of King's College Hospital, and his staff consists of three surgeons, one physician, two anesthetists and a number of medical officers. The fifth unit deals with the reception and distribution of cases and is in charge of a physician of King's College Hospital. Each of the four treatment units will have one "take-in" day out of every four and will receive the bulk of the admissions on that day, though the other units will also be admitting, particularly to the wards earmarked for specialist treatment.

The surgeon in charge of the unit organizes the whole of the work and himself operates as he deems necessary. He reports to the medical superintendent and to the physician and surgeon respectively in charge of the medical and surgical division. The local medical practitioners will also be employed for sessions of two and one-half hours daily. The nurses attached number 700 and have been drafted from London hospitals. Medical students from the London hospitals have been received and a considerable amount of instruction, including lectures, is given. It deals with the kind of cases expected: injuries of the head, chest and abdomen, fractures, burns, wound infections, gas casualties and war neuroses. Even a perambulating museum, which goes in turn to the three hospitals of the sector, has been arranged. This vast disorganization of the peacetime medical service and reorganization of it into a wartime service has been accomplished with celerity and efficiency.

Almost all the London consultants have been mobilized or are on call, and most of them have ceased all other work. But, as seems almost inevitable under the improvised conditions of war, the rates of remuneration have been too crudely laid down. The younger men suddenly find themselves with incomes they could not have expected for years, but the older established ones, with heavy financial obligations, sometimes

are faced with bankruptcy. A plan has been prepared to allow senior men who wish to resume private work to exchange their full time work for part time, so that they can continue their private work.

Prof. G. R. Murray Is Dead

Dr. George Redmayne Murray, emeritus professor of medicine in Victoria University, Manchester, and the discoverer of the thyroid treatment of myxedema, has died. Educated at Cambridge, he graduated with first class honors in the Natural Science Tripos in 1886. He then went to University College Hospital, London, where he had a brilliant career. In 1891 he was appointed pathologist to the Hospital for Sick Children, Newcastle-upon-Tyne, and lecturer in bacteriology, Durham University College of Medicine. He made a great reputation as a teacher and in 1893 was appointed professor of comparative pathology. In 1908 he migrated to Manchester, where he became professor of medicine. His case, which is classic, was published in 1920 in the *British Medical Journal* under the title "The Life History of the First Case of Myxedema Treated by Thyroid Extract."

PARIS

(From Our Regular Correspondent)

Sept. 20, 1939.

Medical Activities of the War

The general opinion of French medical circles is that present war conditions ought not to interrupt the scientific labors of the nation. The limitations placed on medical research by the mobilization of scientific investigators and their assistants and by the curtailment of means of action and work are perhaps partially compensated by the study of special problems caused by the war. Accordingly, all necessary measures have been taken for the continuation of medical activities. The large medical reviews will reduce their editions by about half, either appearing once in every two times or by combining two issues into one. The numerous meetings which were to be held during the autumn have been postponed. However, the large medical societies such as the Société médicale des hôpitaux de Paris, the Société de médecine de Paris and the Société des chirurgiens de Paris have decided to meet as usual; some have even anticipated their regular date. The Académie de médecine met September 12. Instead of the few members usually present the attendance was almost complete. Not only the small body that "holds the fort" during the vacations was present but all who happened to be in Paris came spontaneously, glad to meet one another in these grave times. Many of the academic staff were in uniform, either already assigned to military duties or mobilized in the hospitals with which they are associated. Some of those absent had already been called to the front. Those past the age of military service have for the most part been assigned to special centers.

War increases the number of cases of certain rare maladies. It brings about an increase of wounded with numerous practical problems. It is well known what progress in surgery resulted from the vast clinical experiences of the World War. For that reason the Académie de chirurgie has likewise decided to resume its meetings. Specialized medical centers will be organized, such as the cardiology, psychiatric, tuberculous, syphiligraphic, tropical diseases and neurosurgery. The heads of these centers have not been publicly named, but it is easy to guess them by noting simply the most competent men in each specialty. The functions of these centers will be manifold. They will have to take care of patients who fall within their specialty and seek methods of treatment best adapted to war diseases. Once cured, these patients will be rehabilitated. It will be necessary to determine their exact status and the extent to which participation in military service caused or aggravated their disease, to fix their degree of invalidism—

that is to say, the pension to which they will be entitled—to follow up the rehabilitated and to prepare their readjustment to civil life so that they may be least burdensome to their community. In short, these specialized centers will at the same time be centers of instruction for the physicians at the front and for the students who pursue their studies in uniform.

Scientific Meetings

Hédon and Loubatières pointed out before the Académie des sciences that the quantities of hydrochloric acid exhaled and those of oxygen utilized were normal or even somewhat below normal, tested out in the type of experimental diabetes discovered by Young and determined in the dog by repeated injections of hypophysial extract (anterior lobe) in the peritoneal cavity. These quantities correspond to an expenditure of energy less than 2.5 kilocalories an hour. Young's experimental diabetes differs, accordingly, from the one determined after complete extirpation of the pancreas by the absence of a rise in the basal metabolism. There is also a connection between certain organic disorders, particularly of the central nervous system, noted in those who occupy buildings made of reinforced cement. The metal framework of these buildings constitutes a veritable box such as Faraday used in one of his experiments and creates a constant vibration with the alternating currents, as Denier demonstrated before the Société française d'électrologie et de radiologie.

Lian and his collaborators before the Société française d'hématologie presented an optical method of exploring the coagulation of the blood, based on modifications of the optical density of the plasma in the course of its change from fibrinogen to fibrin. The results are recorded by means of a graph of a particular form which indicates the duration, the beginning and the quality of the coagulation.

(From Our Regular Correspondent)

Sept. 6, 1939.

Reorganization of Studies in Chemistry

In the reconstruction of the medical curriculum, the reorganization of the curriculum of chemical studies has been ordered. To provide uniform training in chemistry, an association had been formed already before the World War by the chemical institutes of the universities to conduct examinations and issue certificates. This preliminary examination had to be passed before one could proceed to work on the doctoral thesis. Formerly, no final examination outside the doctoral thesis existed, certifying that the student had completed a chemical program of comprehensive studies. One could call oneself a chemist without having had a thorough training. Now, however, chemical studies have been given uniformity. No definite course of studies is prescribed for the required seven semesters. The determining factor is the degree of thoroughness, the attainment of which depends solely on the aptitude and industry of the student. The gifted student may thus complete his studies within a shorter time than the prescribed period. Success in passing the examination conferring the chemical diploma opens the way for the doctoral candidacy. The new curriculum of chemical studies divides the student's training into two sections: (1) four semesters of inorganic, organic, physical and physicochemical studies culminating in a "preliminary" examination with diploma and (2) three semesters of "deepened training." In this second phase the student is required to select his major study whether in inorganic, organic, general or technical chemistry. It is based on the assumption that the complexity of chemical studies no longer permits uniform attainments in all the branches of chemistry. This specialized training is attested at its conclusion by a preliminary thesis leading to the diploma and is the pre-

quisite for admission to the main examination. Choice of thesis material should be made with a view of continuing it for the doctor's degree. The "chemist with a diploma" is now a new recognized academic degree.

Control of Malignant Tumors in Danzig

Through regulation of the Danzig senate "a labor association for combating malignant tumors" has been organized. This association is to establish principles for educating the population on the prophylactic examinations to be taken at certain intervals, especially by women, on the kinds of examinations and the treatment of those afflicted. Treatment of malignant tumors may be performed only by physicians. Treatment by mail as well as advice offered on how to cure oneself by means of lectures, pamphlets and so on is prohibited. Physicians are required to conform strictly to the principles established by the labor association. Physicians, public health officials and hospitals must officially report all cases of malignant tumors and suspected tumors within six days. Violations are punishable by fines. Every woman 30 years of age and every man 45 years of age may have themselves examined once a year at the expense of the labor association, which in turn is reimbursed by insurance companies.

ITALY

(From Our Regular Correspondent)

Sept. 15, 1939.

Renal Tumors

The Accademia di Scienze Mediche of the Coneglio and Vittorio regions at a recent meeting discussed renal tumors. Professor Bortolozzi discussed the incidence of renal tumors. He showed a preference for Pugliotti's classification, which is a modification of that of Busser and Obersimmer and is based on morphologic histology. Professor De Gironcoli discussed the symptoms, diagnosis and treatment of renal cancer. Professor Opocher called attention to the importance of urologic disorders for gynecologists. There are so many anatomic, embryologic and physiopathologic interferences between the urinary tract and the female internal genital organs that the conception on the existence of a urologic branch of gynecology is justified. The speaker discussed pyelitis and hydronephrosis in pregnancy, and the reciprocal influence between pregnancy and renal cancer, the coexistence of renal tumors with those of the uterus or of the ovary, vaginal substances from renal carcinoma, metastases to the kidney from chorionepithelioma of the uterus and the possible changes of sexual characters from adrenal tumors.

Renal Complications from Blood Transfusions

Professor Papa, of Naples, in a reunion of the Società Napoletana di Chirurgia, which was held recently, reported results of clinical and experimental work on the behavior of renal functions in blood transfusion which he carried on. He studied the variations of azotemia, the elimination of urea and amino acids through the urine and the possible appearance in the urine of substances which could indicate pathologic involvement after blood transfusion with compatible blood. A patient who had repeated transfusions died from acute renal insufficiency. The speaker found by experiments that the alterations of the renal functions which develop from repeated blood transfusion are due to renal alterations which can be seen during microscopic studies on the kidney. The syndrome which is due to renal blockage may develop suddenly or progressively. The acute syndrome probably develops from spasm of the renal arteries. The chronic syndrome probably develops from a reaction of the kidney to toxic substances which cause alterations of the tubuli and of the glomeruli of the structure.

History of Forceps

Professor Gall of Trieste recently reviewed before the Associazione Medica di Trieste the history of forceps, which were invented by obstetricians of the Chamberlen family, which family used them only when they could obtain large amounts of money from a patient. Roonhuysen, an obstetrician from the Netherlands, bought the instrument from Ugo Chamberlen also with a mercenary purpose. Later Chamberlen bought it back from Roonhuysen. Mauriceau, a Parisian obstetrician, was accused in the poem called "Luciniade" of having retarded the use of forceps in France, but the accusation was false.

Policy of Authorities on Sanitation

The under secretary of state of internal affairs recently lectured before a meeting of the house of representatives. He said that improvement of the race depends on sanitation, the problems of which cannot be solved by bureaucratic centers but by the combined work of large groups of technicians and physicians, especially municipal physicians who are well informed on the problems of local public health. The members of the ministry of internal affairs resolved to elevate the educational and technical standards of officers of public health who work in the various branches of social medicine, especially municipal physicians who are concerned with the prevention and control of diseases. The educational standards of midwives have been elevated also. Administration of antidiphtheric vaccination is compulsory.

Promotion of Assistant University Teachers

The head of the Public Education centers requested from the members of the national board of public education the framing of a bill which concerns assistant teachers in universities. The bill was approved. It provides that assistant teachers in universities who entered by winning a contest or else those who have worked satisfactorily for five years can be either promoted to the position of regular professors in colleges or may be appointed to technical positions in offices of the government.

STOCKHOLM

(From a Special Correspondent)

Sept. 26, 1939.

Artificial Sunlight for Miners

What is certainly unique in Sweden, and probably in the whole of Scandinavia, is a solarium which has been provided by the proprietors of the Boliden mine, whose underground workers can enjoy daylight only on Sundays and for a short daily meal interval from the middle of September to the middle of March. Dr. Johan Pontén, who has played an important part in connection with this solarium, has recently issued a report on its action since it was started in December 1937. The room in which four large quartz lamps and four "solux" lamps were installed measured 5 by 6 meters and was kept at a temperature of from 25 to 30 C. (77 to 86 F.). After changing their clothing and taking a douche or bath, the men would sit naked in the solarium for three minutes every other day, their eyes protected by special glasses.

Wishing to obtain objective and reliable data concerning the effects of such infra-red and ultraviolet radiation on the miners, Dr. Pontén carried out calcium and phosphorus analyses of the blood on twenty-two healthy miners between the ages of 23 and 47. He found an appreciable rise in the average calcium content of the serum from 9.9 mg. per hundred cubic centimeters before the solarium was opened to 10.5 mg. in March 1938, after the solarium had been in use for three months. Another line of research was to compare the morbidity rates among the workers in the Boliden mine before and after the provision of the solarium. Among the 175 underground workers the sickness rate was 9.7 days per head in 1937 and 8.5 in 1938. In the same period there was a reduc-

tion by 12 per cent in the frequency of "one day diseases" and a reduction by 43 per cent of the catarrhal diseases of the respiratory tract. A questionnaire to which anonymous answers were invited showed that a large proportion of the men considered themselves fitter in many respects since they had enjoyed the benefits of the solarium.

Research on Pellagra

The conviction that pellagra can be considered a foreign disease with no practical interest for Swedes has given place to a suspicion that pellagra may be quite common in mental hospitals. At the Beckomberga Mental Hospital, under the direction of Dr. S. Wohlfahrt, five well defined cases of pellagra have been observed in the course of two years. As for the number of early or abortive forms of this disease, accurate information is lacking, for early pellagra presents such vague signs and symptoms that its distinction from a host of other ill defined ailments is most difficult.

Dr. Erland Mindus, who has for some time paid special attention to a twenty-six bed department for women patients in the Beckomberga Hospital, has recently set himself the task of systematically examining all new cases admitted to this hospital for signs of defective gastric activities. He has supplemented test meals with feces examinations and radiologic examinations, and he has found achylia or hypochylia in about 91 per cent of the women patients recently admitted to the hospital. To test his hypothesis that many of these patients with defective gastric secretion were suffering from the beginnings of pellagra, he divided them into two groups as similar as he could make them, and in both the clinical picture was stamped by lassitude, anorexia, depression, loss of weight, simple anemia, insomnia, amenorrhea, hypesthesia, muscular weakness, restlessness and anxiety or apathy. In other words, the clinical picture was that commonly associated with the term "gastrogenic neurasthenia." The first group was given treatment as for pellagra, a stomach extract with hydrochloric acid, extra rations of meat and eggs and, in some cases, vitamin B preparations. The second group, which served as a control, was given the routine treatment heretofore in vogue for such cases in this hospital. The comparatively satisfactory response of the patients in the first group to the special treatment given them suggests that many, if not most, of them may have been suffering from pellagra in a stage too early for the development of the characteristic cutaneous changes.

The Centenary of Ling, the Father of Swedish Gymnastics

On May 3, 1839, the death occurred of Petter Henrik Ling at the age of 63. He was then at the head of the Central Gymnastic Institute, honored at home and abroad. The son of a poor clergyman, he lost his father at the age of 2 and was brought up in most humble circumstances. He graduated at the University of Lund and continued to study in Uppsala. But he never qualified as a doctor. His gifts as a poet and author were full of promise, but it was in gymnastics that he earned a place in the history of medicine. During the century which has passed since his death there have been countless developments in gymnastics, yet the principles he laid down are held to be as sound today as they were when his forceful personality was behind them. The Central Gymnastic Institute, which he founded, has remained ever since as a school for the teaching of gymnastics in health and disease and it has maintained that high standard which has placed Swedish gymnastics in so prominent a position in the world. He made gymnastics a national movement which, beginning in the schools and soldiers' camps, came to inspire the whole community. Throughout Sweden this year Ling's memory is being paid tribute to, and it is no mere chance that the Swedish govern-

ment is opening this year an institution for the teaching of the physiology and hygiene of bodily exercises.

At first, the public was inclined to jeer at a man fanatically devoted to the light he followed. But the medical profession took him and his cause seriously, and the Swedish Medical Society honored itself by electing him a member in 1831. He seems to have been as frail of body as he was forceful of spirit. As a young man he was told by his doctor that he was suffering from consumption. After his death the examination proved this diagnosis to have been correct and showed that death was due to malignant disease of the liver. He was subject to violent attacks of coughing and his respiration was labored, but the vitality of his spirit dominated the frailty of his body throughout his life.

Marriages

FRANK M. WARDER, Glasgow, Ky., to Miss Irene Katherine Randolph of Detroit Lakes, Minn., in Rushville, Ind., August 11.

WARREN A. SMITH, Berrien Springs, Mich., to Mrs. Ruth Cameron of Kalamazoo, in South Bend, Ind., in August.

ROBERT GARFIELD RICKERT, Ann Arbor, Mich., to Miss Miriam Irene McCausey of Highland Park, August 22.

ALEXANDER H. SNEDDON to Mrs. Wilma McLaughlin Dugan, both of Cambridge, Ohio, in New York, August 18.

HOWARD PLEAS WHEELER, Georgetown, Texas, to Miss Mary Josephine Davidson of Fort Worth, August 17.

STAMATIS GEORGE VELONIS, Nespelem, Wash., to Miss Helma Stuart Ross at Northampton, Mass., July 8.

HUGH ALFRED WATSON, Queens Village, N. Y., to Miss Almeria Russ at Hendersonville, N. C., July 28.

JOHN KENT FINLEY, Philadelphia, to Miss Margaret Sheehan Gindhart of Ventnor, N. J., September 6.

GEORGE W. SMELTZ, Pittsburgh, to Miss Callie Waldran of Washington, D. C., in Baltimore, August 2.

ALBERT J. TANNY to Miss Rose McDermott, both of Albuquerque, N. M., at Santa Fe, September 5.

JOHN HOGE WOOLWINE JR., Blacksburg, Va., to Miss Frances Wellons of South Roanoke, September 2.

JOHN I. RINNE JR., Anderson, Ind., to Miss Madge Goldman of Marengo, at Seymour, August 31.

GEORGE KENNETH SCHOLL to Miss Dorothy Ophelia Rhea, both of Johnson City, Tenn., August 25.

HARRY ORR VEACH, Los Angeles, to Miss Pauline Manchester of South Pasadena, August 13.

TERENCE ALOYSIUS KEMPF, Omaha, to Miss Frances Anne Rochford of Colon, Neb., August 26.

CARROLL B. SHADDOCK JR., Beaumont, Texas, to Miss Hulda Martha Gaertner of Malone, July 22.

CHARLES H. MOSELY JR., Monroe, La., to Miss Florent Jane Morley of Rayville, August 5.

WILLIAM C. SPRING JR., Glen Ridge, N. J., to Miss Louell Clark of Jefferson, Ohio, in August.

RUSSELL B. WILLIAMS, Downsville, N. Y., to Miss Auvra May Keith of Salem, Va., July 27.

RALPH N. REDMOND, Sterling, Ill., to Miss Katherine Baxte of Cedar Rapids, Iowa, August 1.

FREDERICK J. GRABER, Stockport, Iowa, to Mrs. Gladys B. Hiatt of Toledo, September 2.

CHARLES FREDERIC STONE JR. to Miss Hazel Hart Smith both of Boston, in September.

WILLIAM CURTIS STIFLER JR. to Dr. JEAN EVANS ROSE both of Baltimore, July 29.

HERBERT KAPLAN, Collegeville, Pa., to Miss Cora Petermar of Limcrick, October 7.

BERNARD P. WOLFF, Atlanta, Ga., to Miss Douschka Brown of Marietta, August 3.

ELLIS K. VAUBEL, Dysart, Iowa, to Miss Helen Christenson of Royal, August 18.

PHILIP ROCHE to Miss Susan Foulke Yocom, both of Philadelphia, August 7.

Deaths

Albert Coulson Buckley * Philadelphia; Medico-Chirurgical College of Philadelphia, 1897; professor of psychiatry, University of Pennsylvania School of Medicine and the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; associate professor of normal histology at his alma mater, 1899-1908, and associate professor of psychiatry, 1908-1917; member of the American Neurological Association, American Psychiatric Association and the Association for Research in Nervous and Mental Disease; past president of the Philadelphia Psychiatric Association; medical superintendent of the Friends Hospital; served in various capacities on the staffs of the Philadelphia General Hospital and the Philadelphia Orthopedic Hospital; author of "Nursing Mental and Nervous Diseases"; aged 66; died, August 17, of pneumonia.

Ernest Charles Dickson * San Francisco; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1906; professor of public health and preventive medicine, emeritus, Stanford University School of Medicine, assistant professor of pathology, 1910-1913, assistant professor of medicine, 1913-1918, associate professor of medicine, 1918-1923, professor of medicine, 1923-1926, and later professor of public health and preventive medicine; instructor of pathology and bacteriology, Cooper Medical College, 1908-1910; member of the Association of American Physicians; on the staff of the Stanford University Hospitals; aged 58; died, August 23, of cerebral hemorrhage.

Louis Daniel Englerth * Philadelphia; Jefferson Medical College of Philadelphia, 1914; F.R.C.S., Edinburgh, Scotland, 1919; fellow of the American College of Surgeons; served during the World War; formerly assistant demonstrator of clinical surgery at his alma mater; surgeon to the Frankford, Philadelphia General, and St. Joseph's hospitals and North-eastern Hospital of Philadelphia; consulting surgeon to the Grandview Hospital, Sellersville; aged 50; died, August 16, in the Jefferson Hospital of hypertensive cardiovascular disease.

Frank Henry Hagaman * Jackson, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1918; president of the Central Medical Society; member of the Southern Surgical Association and the Southeastern Surgical Congress; fellow of the American College of Surgeons; served during the World War; on the staffs of the Mississippi State Tuberculosis Sanatorium, Sanatorium, and the Mississippi State Charity and the Mississippi Baptist hospitals; aged 43; died, August 19, of injuries received in an automobile accident.

Willis Ellis Hartshorn * New Haven, Conn.; University of Minnesota Medical School, Minneapolis, 1898; clinical professor of surgery, Yale University School of Medicine; member of the New England Surgical Society; fellow of the American College of Surgeons; attending surgeon to the New Haven Hospital; consulting surgeon to the Griffin Hospital, Derby, Grace Hospital, New Haven, and chief of staff of the surgical clinic, New Haven Dispensary; aged 67; died, August 4.

Joseph Francis Ward, Brooklyn; Baltimore University School of Medicine, 1899; served during the World War; past president of the Brooklyn Society of Internal Medicine; for many years a member of the board of managers and also consulting physician and psychiatrist of the Craig Colony, Sonyea; formerly chief of the diagnostic research laboratory of the Victory Memorial Hospital; aged 67; died, August 10.

Andrew Martin Gillen, Brooklyn; Long Island College Hospital, Brooklyn, 1897; member of the Medical Society of the State of New York; honorary surgeon in the police department; chairman of the medical board and chief obstetrician at the Shore Road Hospital; on the staff of the Hospital of the Holy Family and St. Mary's Hospital; aged 64; died, August 15, in the Long Island College Hospital.

William Chester Billings * Medical Director, U. S. Public Health Service, retired, La Canada, Calif.; Harvard Medical School, Boston, 1894; was commissioned an assistant surgeon in the U. S. Public Health Service, Dec. 28, 1898, and was retired as a medical director, Oct. 1, 1933; aged 67; died, August 16.

Flaviano E. Parodi, New York; Regia Università degli Studi di Genova Facoltà di Medicina e Chirurgia, Italy, 1891; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; visiting surgeon to the Columbus Hospital; died, August 23, in the Mount Sinai Hospital.

Hugh Francis Flaherty, Hartford, Conn.; Yale University School of Medicine, New Haven, 1907; member of the Connecticut State Medical Society; past president of the board of health; aged 59; on the staff of St. Francis Hospital, where he died, August 24, of arteriosclerosis and chronic nephritis.

Alice Zelia Patterson-Murphy, Flushing, N. Y.; Boston University School of Medicine, 1896; formerly adjunct professor of anatomy at the New York Medical College and Hospital for Women, New York; aged 64; died, August 21, in Newton Highlands, Mass., of brain tumor.

James L. Shuler * Durant, Okla.; Arkansas Industrial University Medical Department, Little Rock, 1887; secretary and past president of the Bryan County Medical Society; medical director of the Bryan County Hospital; aged 79; died, August 24, in Hobbs, N. M., of chronic nephrosis.

Theodore Chamberlin, Concord, Mass.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; formerly district medical examiner and consulting physician to the Middlesex School and the Concord Reformatory; aged 71; died, August 8.

Jackson Joseph Ayo * Jackson, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1893; superintendent of the East Louisiana State Hospital; member of the state board of medical examiners; for many years parish coroner; aged 70; died, August 18.

Charles Prevost Grayson * Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1881; emeritus professor of laryngology at his alma mater; member of the American Laryngological Association; aged 79; died, August 16, of cirrhosis of the liver.

Ellis Henry Milton, Mount Eden, Ky.; Hospital College of Medicine, Louisville, 1892; Southwestern Homeopathic Medical College and Hospital, Louisville, 1898; aged 74; died, July 17, in the King's Daughters Hospital, Shelbyville, of an abdominal malignant condition.

Floyd Ashley Thomas, Flemington, N. J.; Medico-Chirurgical College of Philadelphia, 1907; member of the Medical Society of New Jersey; served during the World War; member of the board of health; aged 57; died, August 9, of coronary thrombosis.

Frank Jackman Sherman * Ballston Spa, N. Y.; University of Vermont College of Medicine, Burlington, 1880; for many years health officer; aged 80; on the staff of the Benedict Memorial Hospital, where he died, August 25, of coronary sclerosis.

Henry Sprince * Lewiston, Maine; McGill University, Faculty of Medicine, Montreal, Que., Canada, 1923; served during the World War; aged 41; on the staff of the Central Maine General Hospital, where he died, August 4, of sarcoma of the sacrum.

Fred Barrington Sutherland, Wolfeboro, N. H.; Cooper Medical College, San Francisco, 1892; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; aged 70; died, August 11, of cerebral hemorrhage.

Nathan Easterly Hartsook * Johnson City, Tenn.; Medical College of Virginia, Richmond, 1895; past president of the Washington County Medical Society; on the staff of the Appalachian Hospital; aged 70; died, August 10, of coronary thrombosis.

Charles William Courville, Detroit; Detroit College of Medicine, 1906; member of the Michigan State Medical Society; diagnostician for the city board of health; on the staff of the Providence Hospital; aged 58; died, August 31, of coronary thrombosis.

James Edward Mansfield, Oswego, N. Y.; Dartmouth Medical School, Hanover, N. H., 1897; member of the Medical Society of the State of New York; for many years health officer; aged 69; on the staff of the Oswego Hospital; died in July.

Helmina Jaidell * Denver; Johns Hopkins University School of Medicine, Baltimore, 1912; member of the American Academy of Pediatrics; aged 60; died August 10, at St. Luke's Hospital of postoperative ileus and chronic intestinal obstruction.

David Forrest Kirkpatrick, Lewisville, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1885; Medical Department of Tulane University of Louisiana, New Orleans, 1887; aged 78; died, August 20, of carcinoma of the bladder.

Clarence H. Willis * Barnesville, Ga.; Atlanta College of Physicians and Surgeons, 1906; past president of the Lamar County Medical Society; aged 57; died, August 15, at the Middle Georgia Hospital, Macon, of cerebral hemorrhage.

Charles Miner Miller Jr. ☉ Olive View, Calif.; University of Pittsburgh School of Medicine, 1928; served during the World War; on the staff of the Olive View Sanatorium; aged 45; died, August 27, of a self-inflicted bullet wound.

Harold Cintra Cox, New York; University of Virginia Department of Medicine, Charlottesville, 1921; member of the Medical Society of the State of New York; aged 44; on the staff of the French Hospital, where he died, August 25.

John Harrison Timberman, Chillicothe, Mo.; St. Louis University School of Medicine, 1906; member of the Missouri State Medical Association; served during the World War; aged 62; died, August 22, of cerebral hemorrhage.

James Gregory Marron, Lincoln, Neb.; Bellevue Hospital Medical College, New York, 1887; member of the Nebraska State Medical Association; veteran of the Spanish-American War; aged 75; died, August 19, of cardiac infarction.

Percival Walter Darrah, Leavenworth, Kan.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; member of the Kansas Medical Society; on the associate staff of St. John's Hospital; aged 67; died in August.

Loren Wilder ☉ Chicago; Rush Medical College, Chicago, 1901; fellow of the American College of Surgeons; chief of the surgical staff of the Edgewater Hospital; aged 66; died, August 19, of cerebral hemorrhage and arteriosclerosis.

Fred Farley Carpenter, Pella, Iowa; Drake University Medical Department, Des Moines, 1897; member of the Iowa State Medical Society; veteran of the Spanish-American War; aged 69; died, August 6, of coronary occlusion.

John Wesley Page ☉ Jackson, Mich.; University of Pittsburgh School of Medicine, 1914; aged 59; on the staffs of the Jackson Clinic and the W. A. Foote Memorial Hospital, where he died, August 22, of coronary occlusion.

Allen C. Holliday, Athens, Ga.; University of Georgia Medical Department, Augusta, 1884; member of the Medical Association of Georgia; for many years member of the board of education; aged 75; died, August 20.

Emil Otto Jellinek, San Francisco; Medizinische Fakultät der Universität Wien, Austria, 1892; served during the World War; formerly on the staff of the Mount Zion Hospital; aged 73; died, July 22, of coronary occlusion.

Isaac Sherman Clark, Long Beach, Calif.; Keokuk (Iowa) Medical College, 1898; member of the California Medical Association; aged 66; died, August 3, in St. Luke's Hospital, Spokane, Wash., of coronary thrombosis.

Jacob Heckmann ☉ New York; Hessische Ludwigs-Universität Medizinische Fakultät, Giessen, Hesse, Germany, 1896; on the staff of the Misericordia Hospital; aged 68; died, August 13, of coronary thrombosis.

Jefferies Buck ☉ Baltimore; University of Pennsylvania Department of Medicine, Philadelphia, 1895; aged 68; died, August 14, in the Union Memorial Hospital of arteriosclerosis and hypertensive cardiovascular disease.

Stanley B. Dickinson, Portland, Ore.; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1897; aged 68; died, July 22, in the Veterans Administration Facility of coronary sclerosis.

George Adelbert Emard ☉ Mansfield, Mass.; Tufts College Medical School, Boston, 1918; for many years on the staff of the Sturdy Memorial Hospital, North Attleboro; aged 56; died, August 3, of cerebral hemorrhage.

Charles C. Ross ☉ Clarion, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; secretary of the Clarion County Medical Society; county health officer; aged 72; died, August 5, of heart disease.

Haynes Watts Brownfield, Anthony, Kan.; Hospital College of Medicine, Louisville, Ky., 1901; member of the Kansas Medical Society; aged 59; died, August 2, of Buerger's disease and carcinoma of the bladder.

Burkert Clark ☉ Hamilton, Ohio; Miami Medical College, Cincinnati, 1901; served during the World War; aged 65; died, August 25, in the Veterans Administration Facility, Dayton, of cerebral arteriosclerosis.

George Thomas Laman, Cave City, Ark. (licensed in Arkansas in 1904); for many years member of the school board; member of the Arkansas Medical Society; aged 57; died, August 8, of angina pectoris.

Cyrille Phedora Verdon, Granby, Que., Canada; Laval University Faculty of Medicine, Quebec, 1895; Laval University Medical Faculty, Montreal, 1896; aged 66; died, July 24, of carcinoma of the esophagus.

William O. Bailey, Louisville, Ky.; University of Louisville Medical Department, 1888; member of the Kentucky State Medical Association; aged 76; died, August 4, in the Jewish Hospital of cerebral hemorrhage.

James Samuel Hyde, Fall River, Mass.; Columbia University College of Physicians and Surgeons, New York, 1902; aged 65; died, August 9, in the Union Hospital of diabetes mellitus and bronchopneumonia.

August Omer Truelove, Fort Wayne, Ind.; Indiana University School of Medicine, Indianapolis, 1915; served during the World War; aged 57; died, August 7, in St. Joseph's Hospital of pernicious anemia.

Charles Pusey McCracken, Colorado Springs, Colo.; University of Arkansas School of Medicine, Little Rock, 1918; member of the Colorado State Medical Society; aged 45; died, August 21, of myocarditis.

William L. Turner, Springfield, Mo.; Barnes Medical College, St. Louis, 1906; member of the Missouri State Medical Association; aged 68; died, August 30, in a local hospital of injuries received in a fall.

Clovis Hiram Robinson, Crane, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1937; member of the State Medical Association of Texas; aged 28; died, July 22, of nephritis.

Harry Thompson Liggett, Louisville, Ky.; Kentucky School of Medicine, Louisville, 1905; served during the World War; aged 64; died, August 17, in St. Joseph's Infirmary of staphylococci septicemia.

William Coleman Rountree, Fort Worth, Texas; University of Tennessee Medical Department, Nashville, 1895; aged 69; died, August 2, of hypertensive heart disease, nephritis and cerebral hemorrhage.

Samuel Augustus Sturm, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1895; member of the Medical Society of the State of Pennsylvania; aged 78; died, August 11, of carcinoma of the nose.

Arthur Lavoie, Sillery, Que., Canada; M.B., Laval University Medical Faculty, Montreal, 1886, and L.M., in 1888; M.D., Laval University Faculty of Medicine, Quebec, 1908; aged 75; died in August.

Joseph Alexander McCready, Greenwich, Ohio; Bellevue Hospital Medical College, New York, 1875; member of the Medical Society of the State of Pennsylvania; aged 91; died, August 18, of senility.

Homer Bowen, Walterboro, S. C.; University of Georgia Medical Department, Augusta, 1911; member of the South Carolina Medical Association; aged 52; died, August 26, of cerebral hemorrhage.

Everett Dayton Knight ☉ Anderson, Ind.; Indiana University School of Medicine, Indianapolis, 1925; aged 38; on the staff of St. John's Hospital, where he died, August 5, of cerebral hemorrhage.

S. W. Williams, Gassaway, Tenn. (licensed in Tennessee in 1910); formerly bank president and member of the board of education of Cannon County; aged 58; died, August 19, of coronary embolism.

Raymond Fox Roller ☉ Altamont, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1913; at one time mayor; aged 55; died, August 11, of cerebral hemorrhage.

Eugene Rischelle Delong, Geigertown, Pa.; Jefferson Medical College of Philadelphia, 1891; member of the Medical Society of the State of Pennsylvania; aged 69; died, July 27, of heart disease.

Carl Frederick C. Kramer, Chicago; University of Illinois College of Medicine, Chicago, 1909; aged 66; for many years on the staff of the Belmont Hospital; died, August 6, of heart disease.

Napoleon B. Houser, Charlotte, N. C.; Leonard Medical School, Raleigh, 1891; formerly on the staff of the Good Samaritan Hospital; aged 69; died, August 28, of cerebral hemorrhage.

Paul Clark Gilson, San Leandro, Calif.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1937; aged 29; died, July 10, of an overdose of sleeping capsules taken accidentally.

Ellis Brown Rhodes ☉ East Cleveland, Ohio; Western Reserve University Medical Department, Cleveland, 1897; aged 66; died, August 7, at his home in Shaker Heights of carcinoma of the colon.

Irving Jerome Bleiweiss, Cleveland; The School of Medicine of the Division of Biological Sciences, University of Chicago, 1933; aged 33; died, August 30, in Chicago of cardiovascular disease.

Robert J. Gauldin, Dallas, Texas; St. Louis College of Physicians and Surgeons, 1900; member of the State Medical Association of Texas; aged 69; died, August 5, of intestinal obstruction.

David Joseph Hetrick, Harrisburg, Pa.; Jefferson Medical College of Philadelphia, 1897; member of the Medical Society of the State of Pennsylvania; aged 67; died, July 11, of coronary occlusion.

George Wilkinson, Jersey City, N. J.; Bellevue Hospital Medical College, New York, 1882; member of the Medical Society of New Jersey; aged 77; died, August 17, of arteriosclerosis.

Rupert William Ford, Otego, N. Y.; Albany (N. Y.) Medical College, 1899; member of the Medical Society of the State of New York; aged 65; died, August 17, of angina pectoris.

William Colfax Roberts, Owatonna, Minn.; University of Michigan Homeopathic Medical School, Ann Arbor, 1899; aged 70; died, August 25, of coronary thrombosis and chronic myocarditis.

Howard Conover, Barnegat, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1905; member of the board of health; aged 61; died, August 13, of cardiac insufficiency.

James H. Fargher ☉ La Porte, Ind.; Chicago Homeopathic Medical College, 1903; on the staff of the Holy Family Hospital; aged 64; died, August 6, of coronary thrombosis.

Minnie Agnes Hinch Conley, Wilmette, Ill.; Northwestern University Woman's Medical School, Chicago, 1901; aged 64; died, August 31, of chronic myocarditis and arteriosclerosis.

Annette B. Fiske Pomeroy, Pontiac, Mich.; Michigan College of Medicine and Surgery, Detroit, 1901; aged 77; died, August 26, in Stoney Point, of myocarditis and arteriosclerosis.

Heinrich Vogel, New York; Albertus-Universität Medizinische Fakultät, Königsberg, Prussia, 1896; aged 64; died, July 19, in Washington, D. C., of carcinoma of the sigmoid.

D. E. Bridgefarmer, McKinney, Texas (licensed in Texas under the Act of 1907); aged 80; died, July 22, of cerebral hemorrhage, hypertensive heart disease and arteriosclerosis.

C. Hector Sexton, Dunn, N. C.; University of Maryland School of Medicine, Baltimore, 1890; aged 83; died, August 30, in the Good Hope Hospital, Erwin, of coronary sclerosis.

Stephen A. Cunningham, Marietta, Ohio; Medical College of Ohio, Cincinnati, 1890; member of the Ohio State Medical Association; aged 71; died, August 14, of heart disease.

Claude Ely Simons, San Diego, Calif.; Hering Medical College, Chicago, 1902; aged 58; died, August 19, in San Francisco of coronary thrombosis and arteriosclerosis.

G. Howard Wilson, Dalton City, Ill.; National Normal University College of Medicine, Lebanon, Ohio, 1896; aged 67; died, August 31, of amyotrophic lateral sclerosis.

Albert Lafayette Foster, Corryton, Tenn.; National University Medical Department, Washington, D. C., 1897; for many years postmaster; aged 74; died in August.

Reuben L. Hust, Albuquerque, N. M.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; aged 69; died, August 19, of cerebral hemorrhage and leukemia.

William M. Edgerton, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1896; aged 69; died, August 4, of coronary sclerosis.

Robert Joseph Carey, North Brookfield, Mass.; Yale University School of Medicine, New Haven, Conn., 1928; aged 36; died, August 20, in Boylston of tuberculosis.

George W. Antoine, Houston, Texas; Meharry Medical College, Nashville, Tenn., 1906; served during the World War; aged 60; died, August 17, of heart disease.

Frank William Hewes, Groton, Conn.; University of Vermont College of Medicine, Burlington, 1894; aged 72; died, August 18, of carcinoma of the intestine.

George Henry Littlefield, Boston; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1878; aged 91; died, August 18, in the City Hospital.

John O. Briscoe, Weslaco, Texas; Missouri Medical College, St. Louis, 1887; aged 79; died, July 24, in Mission of complications following a fractured hip.

William Yancey White, Center, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1887; aged 78; died, August 11, of coronary occlusion.

Walter Odesly House, Tarboro, N. C.; Medical College of Virginia, Richmond, 1927; aged 41; was killed, August 22, near Nashville in an airplane accident.

Jesse Howard Hutten, Omaha; Howard University College of Medicine, Washington, D. C., 1898; aged 68; died, August 11, in Los Angeles of heart disease.

David Henry Braden, Wooster, Ohio; Homeopathic Hospital College, Cleveland, 1895; aged 71; died, August 13, of carcinoma of the liver and rectum.

Ben C. Crisler, Aberdeen, Miss.; College of Physicians and Surgeons, Memphis, Tenn., 1907; aged 52; died, August 10, of poisoning by carbolic acid, self administered.

Gilbert Leroy Pray, Lake City, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; aged 63; died, August 19, of bronchopneumonia.

Orley Haven Van Eman ☉ El Centro, Calif.; College of Medical Evangelists, Los Angeles, 1924; aged 40; died, August 24, of a self-inflicted bullet wound.

Sylvester Sutton Hamilton, Punxsutawney, Pa.; Columbus (Ohio) Medical College, 1878; aged 86; died, August 2, of a fractured hip received in a fall.

Wen Galaway Cutts, Pittsburgh; Detroit College of Medicine, 1909; aged 66; died, July 10, in St. Francis Hospital of carcinoma of the prostate.

John August Rolfs, Aplington, Iowa; Drake University College of Medicine, Des Moines, 1904; aged 70; died, August 29, of coronary occlusion.

James Harry Hagan, Lake Forest, Ill.; Drake University Medical Department, Des Moines, 1890; also a pharmacist; aged 76; died, August 27.

Floyd B. Moore, Fairhope, Ala.; Chicago Medical College, 1889; aged 71; died, August 5, of chronic myocarditis and arteriosclerosis.

Alexander A. Friedel, Memphis, Tenn.; Jefferson Medical College of Philadelphia, 1887; aged 79; died, August 1, of arteriosclerosis.

Burt Omen Jerrel, Oskaloosa, Iowa; Chicago Homeopathic Medical College, 1894; aged 70; died, August 17, of coronary occlusion.

Joseph Lafayette Minton, Hartman, Ark.; Missouri Medical College, St. Louis, 1880; aged 85; died, August 7, of pernicious anemia.

Timothy A. Daly ☉ Chicago; Northwestern University Medical School, Chicago, 1897; aged 65; died, August 16, of heart disease.

Edgar Merryman Parlett, San Francisco; Baltimore Medical College, 1902; aged 59; died, August 21, of a self-inflicted bullet wound.

Abraham B. Deany, Winchester, Ky.; Meharry Medical College, Nashville, Tenn., 1903; aged 62; died, August 13, of myocarditis.

Leonidas M. Jones, Harrison, Mich.; Detroit Homeopathic College, 1906; aged 63; died, August 28, of coronary thrombosis.

John William Wills, Wellston, Ohio; Kentucky School of Medicine, Louisville, 1890; aged 76; died, August 14, of pneumonia.

Davis H. Westfall, Polk, Neb.; John A. Creighton Medical College, Omaha, 1902; aged 64; died, August 11, of coronary occlusion.

Lewis Mendelsohn ☉ Jersey City, N. J.; Baltimore Medical College, 1901; aged 66; died, August 26, of pulmonary embolism.

Henry A. Smith, Sumner, Miss.; Missouri Medical College, St. Louis, 1879; aged 81; died, August 1, of coronary occlusion.

Edward Bower Flavien, New Haven, Ind.; Toledo Medical College, 1898; aged 63; died, August 27, of carcinoma of the lung.

David Finley Brown, Hudgins, Va.; Cleveland University of Medicine and Surgery, 1897; aged 82; died, August 15, of senility.

Henry G. Stemen, Lebanon, Ohio; Medical College of Fort Wayne, Ind., 1878; aged 88; died, August 16, of myocarditis.

Henry Robert Hay, Warton, Ont., Canada; Victoria University Medical Department, Coburg, 1887; died, August 21.

William John Beatty, Keewatin, Ont., Canada; Trinity Medical College, Toronto, 1896; died, August 23.

Robert Elice Calhoun, Tulsa, Okla.; Barnes Medical College, St. Louis, 1898; aged 70; died in August.

Bureau of Investigation

THE UNIVERSAL HEALTH FOUNDATION FRAUD

Post Office Closes Mails to F. L. Gailey and Z. Dominguez

Florence L. Gailey, a 70 year old woman, allegedly the widow of a physician who died in 1926, together with 73 year old Zeferino Dominguez, carried on from Los Angeles a rather elaborate piece of mail-order quackery under the trade styles Universal Health Foundation, Goode Products Company and Good Products Company. Mrs. Gailey was president and Mr. Dominguez was vice president of the concern.

The information that follows is based in part on material in the files of the Bureau of Investigation of the American Medical Association and, more largely, on the statements made by Judge Vincent M. Miles, Solicitor for the Post Office Department, in his memorandum to the Postmaster General recommending the issuance of a fraud order. Mrs. Gailey and Dominguez sold through the mails (1) a device called the "Miracle Exerciser," (2) a book entitled "Secrets of How to Live 150 Years" and (3) certain nostrums called, respectively, "Miracle Hemovida Tablets," "Miracle Digestall Tablets" and "Si-Nease Miracle Antiseptic." The business was started in 1931 under the name "The Miracle Exerciser Company," which was changed in 1935 to "Universal Health Foundation." No physicians, pharmacists or chemists were connected with the enterprise, and the nostrums, book and "exerciser" were purchased from other sources.

Mrs. Gailey is said to have told the Post Office officials that she had learned all she knew about the human system from her husband. She declared that she originated the Miracle Exerciser, which, according to the advertising, would prevent not only "senility and loss of sex power" but also "prolapses in all the vital organs" and would, in addition, "stimulate circulation in the scalp" and aid "in all heart disturbances." The Miracle Exerciser consisted of two spiral springs, each with a handle at one end while the other ends were connected by a metal plate or bar. The user was supposed to lie supine with the feet on the bar and a handle in each hand; the bar was to be pushed with the feet and the handles pulled with the hands. One variation in its use was for the user to lie with head hanging over the side of the bed for the alleged purpose of causing greater blood circulation in the head. The mischievous possibilities of such recommendation in cases of elderly people with sclerotic vascular systems may be imagined.

The nostrum "Hemovida" was said by the Gailey-Dominguez concern to be "based on the Nobel Prize Award of 1935"—whatever that might mean. The tablets were reported to contain seaweed (kelp), alfalfa, legume starch, cornstarch, chlorophyll, some animal matter (allegedly liver extract) and small amounts of iron, phosphorus, magnesium, sulfur, sodium and potassium. The "Miracle Digestall Tablets" were essentially of the same composition as Hemovida except that they contained

The Great Importance of
in
Extending the Span
of
HUMAN LIFE
by
F. L. Gailey

The World's Most Eminent Authority Diet-
etic And On Brain Degeneration—caused thru
injurious upright posture of the human body.

"Go Forth Unto Nature and Learn Her
Great Truths and Lessons."

Published 1937 By
UNIVERSAL HEALTH FOUNDATION
221 CONSOLIDATED BLDG.,
LOS ANGELES, CALIF.

no animal matter. The advertising led the public to believe that Hemovida would "produce more healthy red blood cells," would "raise the defenses of the body," "increase vitality" and cure pernicious anemia. The Digestall tablets were claimed to make it possible for oldsters to "retain your youthful appearance throughout the entire span of life." "Si-Nease Miracle Antiseptic" was a mixture of mineral oil and olive oil in which there was 1 per cent ephedrine, ethyl aminobenzoate, carbolic acid, menthol, camphor, eucalyptus and oil of thyme. Government tests were said to show that the stuff had "very weak inhibitory effects upon germs tested in vitro."

The only evidence offered by Gailey-Dominguez was statements from two alleged physicians respecting the claims made by the company. Only one of these statements was sworn and neither was supported by any evidence to show the qualifications of the writers or to show in fact whether those who made them were physicians. The statements were held to be incompetent as medical evidence and their incompetence was even admitted by the attorney for the Universal Health Foundation! Judge Miles expressed the opinion that "some of these alleged doctors' statements appear ridiculous on their face."

Even more preposterous, however, is the claim appearing under the name of F. L. Gailey on the cover of an advertising leaflet, shown (reduced) on this page. The claim reads as follows:

The World's Most Eminent Authority Diet-
etics And On Brain Degeneration—caused thru
injurious upright posture of the human body.

After the hearing in Washington Judge Miles, on going into the matter in detail, declared that the evidence showed that the scheme was a fraudulent one and he recommended that the Postmaster General issue a fraud order closing the mails to the concern. On Feb. 16, 1939, the mails were closed to Universal Health Foundation, Good Products Company, Goode Products Company, F. L. Gailey, president, Zeferino Dominguez, vice president, Z. Cortez, secretary, John Clark, assistant secretary, and their officers and agents as such.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Belding Skin Remidin.—International Stock Food Co., and Dr. Belding Medicine Co., Minneapolis. Composition: Chiefly alcohol, water, glycerin and small amounts of ethyl acetate and mercuric chloride. Its effectiveness as a cure for eczema, rash, scabies, plant poisoning, hives, barber's itch, ringworm, itching "piles," parasitic diseases, dandruff, etc., was fraudulently represented.—[N. J. 29253; December 1938.]

Ingersoll's Gall-Stone Pills, Gall Stone Remedy and System Cleanser.—G. A. Ingersoll Remedy Co., Milwaukee. Composition: Pills, phthalain (0.64 grain in each), small amounts of extracts of plant drugs, salicylate and menthol; Gall Stone Remedy and System Cleanser, a liquid medicine containing essentially a fixed oil, such as olive oil, with sugar and water, cinnamon flavored; and two powders, one a mixture of baking soda and sodium tartrate, and the other, tartaric acid. Representations made for the effectiveness of these nostrums in treating gallstone conditions were declared fraudulent.—[N. J. 29268; December 1938.]

Nature's Herb Tablets.—Washington Herb Co., Washington, D. C. Composition: Plant material, including aloe. Curative effect in blood liver, kidney, rheumatic and stomach disorders, ague, malaria, catarrh, nervous diseases, etc., was fraudulently represented.—[N. J. 29255; December 1938.]

Correspondence

POLIOMYELITIS AND TONSILLECTOMY

To the Editor:—Dr. H. G. Langworthy (THE JOURNAL, September 9, p. 1052) believes that we are unduly overwrought over the relationship of poliomyelitis and the removal of tonsils and adenoids. He states:

Considering that operations for tonsillectomy and adenectomy number possibly one fourth of all major operations that are performed yearly in the country and under all sorts of varying conditions and circumstances, one could well promote almost any idea, however untrue or remote, by citing the occurrence of a few sporadic cases. The removal of adenoids and tonsils, when necessary, is so important in the welfare of children that attempts to raise doubts and issues not clearly proved is to do great harm rather than good. Because a few cases of poliomyelitis occurring in summertime may have appeared after any operation, whatever that operation might accidentally have been, is no reason whatever to raise doubt and fear. If there is an epidemic of poliomyelitis in one's own community, any wise physician under these exceptional circumstances should easily recognize what is the best procedure to adopt. The summertime during the long vacation period is a good time for the removal of tonsils and adenoids in school children and should be consistently encouraged.

It is fairly well established by now, from the experimental, epidemiologic and clinical points of view, that the nasopharynx constitutes the portal of entry for the poliomyelitis virus. Any tissue injury present as a result of operation on the tonsils and adenoids, in the presence of a poliomyelitis epidemic, would tend to increase the susceptibility to the virus.

Silverman (Acute Poliomyelitis in Syracuse, N. Y., *Am. J. Dis. Child.* 41:829 [April] 1931) reported five cases of infantile poliomyelitis following tonsillectomies and adenoidectomies (Fischer, A. E., and Stillerman, Maxwell: Acute Anterior Poliomyelitis in New York, 1935 [A Review of 686 Cases], *Am. J. Dis. Child.* 54:984 [Nov.] 1937).

That a seasonal variation exists, one must remember that the peak of poliomyelitis not infrequently corresponds to the heavy pollen concentration during late August and September months (Felderman, Leon: Acute Anterior Poliomyelitis with Special Reference to Its Rhinological Aspect, *Laryngoscope* 48:802 [Nov.] 1938).

It is a mistake to advise parents that the summer is the ideal time for tonsil and adenoid surgery. As a matter of fact, the cooler months of the year offer the child a more auspicious time without undue risks.

LEON FELDERMAN, M.D., Philadelphia.

PRIMARY TUBERCULOSIS IN ADULTS

To the Editor:—As I have been especially interested in primary tuberculosis in adults for several years and recently published an article on the subject, together with Hedvall (Malmros, Haqvín, and Hedvall, Erik: Studien über die Entstehung und Entwicklung der Lungentuberkulose mit besonderer Berücksichtigung des Verlaufs der tuberkulösen Erstinfektion des Jugendlichen und Erwachsenen, *Tuberkulose-Bibliothek* No. 68, Leipzig, Johann Ambrosius Barth, 1938; reviewed in THE JOURNAL, Dec. 17, 1938, p. 2331), may I be allowed to make a few comments in connection with the editorial entitled "Primary Tuberculosis in Adults" in THE JOURNAL, July 8, page 146. It concerns the following statement: "Primary infection in adults, other things being equal, appears to be . . . no more grave than in children" and in addition the following points from page 147, taken from the article of Myers and his co-workers:

The first infection type of tuberculosis, as observed in this group of adults, has resulted in no significant symptoms or abnormal physical signs throughout the entire course of development. Indeed, he states, the lesions in the majority of their cases would not have been known to exist had it not been for periodic tuberculin tests, and the making of roentgenograms of the positive reactors. It apparently makes no difference at what time of life the first infection with tubercle bacilli occurs with reference to the average type of tuberculosis in human beings.

In order to understand the importance of primary tuberculosis in adults, it is surely essential to study in detail cases in which the tuberculin reaction in adults has changed from negative to positive and to check up on them by frequent roentgenograms during the years immediately following. In our work Hedvall and I have given a report of 151 such cases of primary tuberculosis in adults. Of these, 104 showed no symptoms besides the positive tuberculin reaction. Of the other forty-seven cases, a primary complex or merely enlarged hilus glands could be shown roentgenologically in twenty-one cases. In these cases there usually appeared in connection with the infection general symptoms such as fever, symptoms of influenza, increased sedimentation rate and, in women very often, erythema nodosum. In some cases pleurisy developed after an interval of a few months and in others actual pulmonary tuberculosis resulting from "subprimary initial lesions" in the supraclavicular region. In some of the cases the first sign of tuberculous infection was an exudative pleurisy. The primary infection can also first appear as acute miliary tuberculosis. In all these different forms of primary tuberculosis in adults there generally appeared in connection with the infection, as in children, more or less pronounced general symptoms for which the persons concerned sought medical aid because of feeling ill. Again, in other cases (fourteen) actual tuberculosis of the lungs gradually developed without any general symptoms and often with a normal sedimentation rate. Changes in the lungs were discovered here only by means of systematic roentgen supervision. The first detectable lesions were in the form of "subprimary initial lesions"—diffuse, cloudlike spots of different size, often multiple, and in the majority of cases situated in the supraclavicular region or in the first intercostal space. In a considerable number of cases the initial apical lesions were the first manifestation of a progressive type of pulmonary tuberculosis. The conditions found in those cases in which the tuberculin reaction was positive at the time of the first examination corresponded well with those in the aforementioned group of cases. A subclavicular infiltrate of the Assmann type was only rarely found to be the earliest lesion.

As is evident from the foregoing, primary tuberculosis in adults can appear in different forms. In some cases the infection gives pronounced general symptoms; then enlarged hilus glands are most often found, and sometimes a typical primary complex. In many cases, however, progressive tuberculosis of the lungs develops in close connection with the infection (already after a few months) without the person concerned feeling ill. It may be of great interest to know of this form of primary tuberculosis in adults, for it can be discovered only by systematic roentgen examinations. It is possible, and perhaps likely, that it is just this form of tuberculosis which is the cause of the high morbidity and mortality in tuberculosis of the lungs in persons between the ages of 20 and 30. In any case, one must probably count on the fact that primary infection in adults is more grave than in children, for among children, as is well known, one finds progressive tuberculosis of the lungs rather seldom. From the point of view of national economy it might be more important to sacrifice work and money in examining young adults rather than children of school age. As far as I can understand, there has been as yet but slight advantage from all mass examinations (x-ray) of children. On the contrary, one might be able to expect better results from tuberculin and roentgen examinations (with frequent supervision) of young adults.

Lastly, may I draw attention to a little typographic error on page 146. In the report of Heimbeck's examination it says "The highest morbidity was in the nurses who were positive at the time of admission." I presume that the word should have been negative.

HAQVIN MALMROS, M.D., Örebro, Sweden.

TUBERCULOUS WOUND INFECTION AFTER NEPHRECTOMY

To the Editor:—A man aged 44 was operated on six months ago and had a right tuberculous kidney removed. After six weeks the wound broke open and has remained so ever since. I used irrigations of "mercesin" solution, ultraviolet rays, calcium orally and large doses of super D vitamin. There has been little or no improvement during the last six months. The Wassermann reaction is negative and x-ray examination of the chest is negative. I have been advised that tuberculin might be of some value. Kindly advise me whether you feel that it is worth a trial and as to the method of use. Victor P. Dalo, M.D., Louisville, Ky.

ANSWER.—It is evident that the patient has a widespread tuberculous infection of his wound. The reason of this occurrence in an occasional case has been the subject of much speculation. Among the theories advanced are the following: 1. The wound becomes infected from the ureteral stump. 2. Some of the perineal fat that has been left behind harbors tubercle bacilli and, following surgical trauma, breaks down, and so the wound becomes infected. 3. A short time ago a new theory was advanced to the effect that these wounds become infected by the blood stream.

As far as treatment is concerned, there are two schools of thought—the one is medical and the other is surgical. The adherents of the medical point of view in the management of tuberculous wounds advise plenty of rest in bed, lots of sunshine or the use of ultraviolet rays, cod liver oil and the like; in other words, a general program of management such as one employs in any case of tuberculosis. The treatment of the wound consists of dry dressings and the occasional applications of Peruvian balsam. Under this sort of a program most of these wounds heal, although it takes a long time.

The surgical school believes in closing the wounds by operation, removing the tuberculous tissue by means of a dull curet and suturing the wound with silver wire. While healing may be slow under the medical program, the wound generally heals. It is to be remembered that after operation the wound may again become infected and break down.

The use of tuberculin is not advised. It might be advisable to try dressings of cod liver oil.

ATROPINE AND ITS DERIVATIVES

To the Editor:—1. Would you please inform me whether any of the newer atropine preparations, such as novatropine and syntropan, have advantages over the time-honored extract and tincture of belladonna and atropine sulfate? 2. Will the administration of the extract of belladonna, one-fourth grain three times a day, or of atropine sulfate, $\frac{1}{4}$ grain three times a day, produce therapeutic effects on the gastrointestinal tract equal to those obtained by the usual increasing doses of tincture of belladonna? 3. Does the extract of belladonna have any advantage over atropine sulfate? It seems more usually prescribed when capsules or pills are desired, especially in combination with other drugs.

M.D., New York.

ANSWER.—The synthetic substitutes for atropine have been prepared to overcome the side actions which limit the use of atropine in full dosage. These undesirable side actions of atropine which occur when atropine is used in full therapeutic dosage over a period of time include extensive drying of the mucous membranes and skin, a persistent mydriasis, a rapid heart due to the action on the vagus, and a continual desire to micturate. Larger doses may produce more serious manifestations and restlessness. Also in persons over the age of 50 and in those with a tendency to an increased intra-ocular tension the tendency of atropine to increase this condition must not be disregarded. Novatropine and syntropan are both included in New and Nonofficial Remedies for 1939.

Atropine or belladonna is frequently used over an extended period in the treatment of gastrointestinal conditions to reduce spasm of the smooth muscle and also to reduce the secretion of hydrochloric acid in the stomach. The newer synthetics, such as those mentioned, will reduce spasm of the smooth muscle, but there is some question as to whether they will inhibit the secretion of hydrochloric acid to the same degree as an equivalent amount of atropine.

1. If relief of spasm of the smooth muscle is desired over a period of time, the synthetics will control this with a minimum degree of the undesirable side actions mentioned.

2. Since the extract of belladonna is a 400 per cent preparation (i. e. 1 Gm. of the extract contains the active principles of 4 Gm. of the crude drug) and since belladonna leaves contain not less than 0.3 per cent of mydriatic alkaloids, one-fourth grain (0.016 Gm.) of the extract contains 0.0002 Gm. ($\frac{1}{500}$ grain) of the total alkaloids. If equivalent quantities of

the tincture which is a 10 per cent preparation are used, equal effect on the gastrointestinal tract will be produced.

3. Belladonna contains eight or more alkaloids. They all have practically the same action on smooth muscle, but some are hypnotic and some stimulating to the cerebral cortex. They are present in the extract in the proportion that they occur in the plant. The activity is due mainly to atropine and hyoscyamine. The latter alkaloid is equivalent to atropine in its central effect. If rather large doses of belladonna are to be used over a period of time, the extract might be more desirable than atropine sulfate, owing to the lessened mental effect of the extract when given in equivalent amounts.

INDUSTRIAL DERMATITIS

To the Editor:—I am seeking information as to the cause of a dermatitis, apparently of occupational origin. With a negative history for any similar condition previous to 1938, the patient broke out with a maculopapular rash confined chiefly to the ventral surfaces of the forearms, which persisted until the middle of April (having started in January); he began this particular work, i. e., as a laborer in a creamery, July 1, 1937, the work consisting chiefly of sterilizing and cleaning equipment. Some of the lesions became pustular and for these he received inoculations with beneficial results. He was free from any recurrence until March 15, 1939, when the condition returned and has persisted since. The itching coming on during the night is most distressing, and from his scratching some pustular lesions develop. The materials used in his work are as follows: (1) a preparation called Pep-Tex, which is a milk-stone remover made by the Diversy Corporation, Chicago; (2) Diversol, a chlorine preparation made by this firm; (3) a boiler compound for cleaning the boilers; (4) a copper polish, which is a reddish powder, and (5) chlorine. It is with this group of things that I hope you will be able to help me, by suggesting causes of such a dermatitis as we have in this instance.

R. S. Quackenbush, M.D., Goshen, N. Y.

ANSWER.—All the substances that the patient uses are potential cutaneous irritants. Pep-Tex contains strong alkalis, such as trisodium phosphate, and sodium silicate mixed with sodium chromate. It will irritate the skin if allowed to remain on it for any length of time. It will also enter cuts and abrasions to form chronic ulcers. In addition to this the sodium chromate may also act as a cutaneous sensitizer.

Diversol is also strongly alkaline and in addition contains sodium hypochlorite, which may itself be a cutaneous irritant.

Boiler compounds are also strongly alkaline, containing such substances as sodium hydroxide, sodium carbonate, trisodium phosphate and sodium fluoride, all of which will irritate the normal skin.

Copper polishes may contain crude sodium carbonate, oxalic acid, oleic acid, quartz or silica. The color may be due to paris red or to iron oxide. The sodium carbonate and the oxalic acid are powerful irritants of the skin.

Chlorine can also irritate the skin.

It is advisable that the treatment in this case consist only in the application of mild lotions or ointments, such as boric acid or calamine, and the wearing of long rubber gloves while working to prevent further contact with any of the irritants.

EPHEDRINE IN RHINOLOGY

To the Editor:—I have been asked to get an opinion as to the use of ephedrine in the treatment of various nasal conditions. The company making this inquiry states that there seems to be some doubt in the minds of the medical profession as to the wisdom of using ephedrine in the treatment of various nasal conditions.

M.D., North Carolina.

ANSWER.—Ephedrine and its salts are drugs of choice for local use in the nose in cases in which the pharmacologic effect of a vasoconstrictor is desired. Thus it is used in acute rhinitis, acute sinusitis and the like. As shown by Proetz and others, ephedrine in weak solutions, from 1 to 3 per cent, has no deleterious effects on ciliary action. In accord with present day thought, ephedrine is best used in physiologic solution of sodium chloride rather than in an oily preparation. It is also well used in weak dilutions, from 0.25 to 0.5 per cent, in the displacement method of treatment as advocated by Proetz.

Although ephedrine is perhaps one of the more important drugs in the treatment of acute and subacute nasal conditions, it must be used with caution in chronic nasal disease. Thus, for example, in vasomotor rhinitis and perennial nasal allergy, in which there is chronic nasal obstruction and the need for relief is constant, ephedrine should be used with caution, for it, as do similar drugs, may act as a sensitizing agent when used indiscriminately. A transient vasoconstriction is followed in many instances by a prolonged vasoparalysis; sneezing, a watery discharge and itching become prominent complaints, and the original disease is much aggravated and prolonged by the very medication intended to relieve it.

DISGUIISING TASTE OF SULFATES

To the Editor:—Please let me know what powder is best used to disguise sulfate as to taste.
F. W. Cobar, M.D., Milwaukee.

ANSWER.—The question as to disguising sulfate is rather general and indefinite, as it does not specify a particular one. It is not the sulfate but rather the specific radical attached that needs disguising.

As to disguising sulfates in the dry form: Magnesium sulfate is least unpalatable in the form of the effervescent salt of magnesium sulfate N. F. VI. Sodium sulfate may also be made into effervescent form. Either is perhaps best taken in ice cold lemonade. Tablets of codeine sulfate, quinine sulfate and strychnine sulfate are official in N. F. VI and can be easily swallowed without having the patient experience the bitter taste. The sulfates that need not be given in too large dosage may be dispensed in capsule form.

As to disguising sulfate in liquid form: Codeine sulfate and strychnine sulfate may be well disguised by the use of compound syrup of eriodictyon N. F. VI. Ephedrine sulfate may be prescribed in cherry syrup and is official in N. F. VI under the title "syrup of ephedrine sulfate."

SMOKING ACETYSALICYLIC ACID WITH TOBACCO

To the Editor:—For the past nine years I have been jail physician and during that time it has been frequently called to my attention that certain inmates were in the habit of crushing tablets of acetylsalicylic acid and putting the powder in tobacco and smoking the mixture. Can you tell me what the effect of the mixture would be from a single smoke and what would be the effect of the continuous use of acetylsalicylic acid in this way?
M.D., District of Columbia.

ANSWER.—A search of the literature has failed to reveal any reports on the effects of inhaling the vapors of acetylsalicylic acid in tobacco smoke. When this drug is mixed with tobacco and smoked as described, several products would be formed and inhaled. Some of the acetylsalicylic acid would probably be volatilized and inhaled as the unchanged acetylsalicylic acid. There would be some salicylic acid and acetic acid inhaled and absorbed and also some other disintegration products of the drug. These substances sensitize the mucous membranes of the respiratory tract and in this way would enhance the effects of the tobacco itself. In addition, the inhalation of the vapors of acetylsalicylic acid would have the usual effect of this drug but to a much greater degree, because of the avenue of entrance into the body. The inhalation of salicylic acid vapors in sufficient amounts produces a nervous exaltation and a cerebral inhibition somewhat resembling that produced by alcohol. This is followed by depression.

It is difficult to say just what the effect of a single smoke would be. The effect of the continuous use of acetylsalicylic acid in this way would vary, just as the continued use in the ordinary way produces different effects in different persons. In addition to the physiologic effect produced by smoking acetylsalicylic acid, the psychic effect in these individuals must not be disregarded.

ATROPINE POISONING

To the Editor:—A patient took an overdose of belladonna about one year ago and still complains of some of the symptoms of acute atropine poisoning. Is it possible for her to have a persistence of these symptoms after such a period of time? My pharmacology textbook states that atropine is fully eliminated in thirty-six hours in the urine. Is it possible that some of the belladonna has become stored somewhere in the body? Her pulse has been 100 or over ever since the poisoning. She breaks out with a measles-like rash over the back every now and then. She has lost her sense of smell.
M.D., California.

ANSWER.—The size of the overdose of belladonna is not given, so that it is difficult to predict the possible effects. Doses of belladonna, of both the tincture and the fluidextract in amounts up to ten times the U. S. P. doses, have been administered over a period of time without any harmful effects persisting after the drug was stopped.

Atropine, to which the effects of belladonna are mainly due, is rapidly absorbed by mucous membranes and the intestine. If atropine is given in ascending dosage to animals over a period of time, the drug may be stored in their flesh for several days and this flesh may produce atropine intoxication in other animals if it is consumed in sufficient quantities. It disappears rapidly from the blood and is excreted, mostly unchanged, entirely by the urine, mainly within thirty-six hours. In acute atropine poisoning the effects are felt in an hour or less, while in slower poisoning the full effect may not develop for one or two days.

In both cases the effects gradually pass off. The mydriatic action may persist two weeks and the mental or psychic symptoms even longer. Idiosyncrasy to the belladonna group is quite frequent.

In the case described it is extremely improbable that the symptoms of acute belladonna poisoning could persist after a year. The rapid pulse and the occasional measles-like rash point to an unstable vasomotor system. The drug could not now be active on the vagus, and the rash is certainly not due to any retained atropine. It is more probable that the patient is of the nervous type and is susceptible to suggestion. If she can be really convinced that there is no longer any retention of the drug her symptoms may disappear.

MAGNETS FOR REMOVAL OF OCULAR FOREIGN BODIES

To the Editor:—Will you kindly furnish me with some information regarding magnets for removal of intra-ocular foreign bodies? Are the inexpensive magnets now advertised by reputable instrument houses satisfactory for this work? These work on alternating current with no rectifier and, I believe, cost less than \$15.
M.D., Alabama.

ANSWER.—The value of a magnet in the removal of intra-ocular foreign bodies depends on the strength and extent of the magnetic field. The more powerful the magnet, the simpler is the extraction and the less trauma does the eye suffer. For fairly superficial foreign bodies or for such as are located in the anterior chamber and can be removed through a simple keratome incision, the simpler and hence weaker magnets suffice. But for the foreign bodies that have penetrated deeply and as a result of time may be tightly embedded in ocular tissues, the most powerful magnet is none too strong. A comparison of the relative value of magnets is not available, but the most satisfactory of all the magnets on the market is the one that was devised a few years ago by Dr. Walter B. Lancaster of Boston.

PERSISTENT PAIN FROM SYPHILITIC PERIOSTITIS

To the Editor:—Kindly advise me how to control pain and tenderness in syphilitic periostitis that has apparently been resistant to analytic treatment. A woman aged 27, without a history of initial or secondary lesions, complained of pain in both shins at night. X-ray examination of the tibia was negative; serologic examination of the blood was positive, and the spinal fluid was normal. During the past year she has had thirty injections of mapharsen and of nearsphenamine, sixty injections of bismuth and large doses of potassium iodide. The pain and tenderness in the tibia, clavicles and calvarium have never been relieved completely. Blood studies showed a slight hypochromic anemia but no signs of blood dyscrasia. Serologic examination of the blood is still positive.
M.D., Indiana.

ANSWER.—The persistence of the pain in the tibia, clavicles and calvarium following the amount of treatment that this patient has been given and the negative x-ray examinations would suggest some factor other than syphilis as the cause of the difficulty. As a rule the "night pains" of syphilis disappear readily following several injections of an arsenical preparation, but occasionally patients with osseous syphilis derive a more pronounced benefit from the intramuscular use of a mercuric preparation. If further search reveals no other explanation for the discomfort, a course of twenty injections of mercuric succinimide, one-sixth grain (0.01 Gm.), in conjunction with large doses of potassium iodide, up to fifty drops three times a day, should be tried.

ROENTGEN THERAPY IN BONE TUBERCULOSIS

To the Editor:—May I have a brief statement of the present value of roentgen therapy for bone and joint tuberculosis, especially the elbow joint and the ulna?
Arnold Bockar, M.D., Warwick, N. Y.

ANSWER.—Tuberculosis affecting bones and joints often responds well to roentgen treatment but, like tuberculous processes in general, the response is usually slow. As in all chronic inflammations that are amenable to roentgen treatment, tuberculous lesions of bones and joints are best treated by doses corresponding to about three fourths of an erythema dose, and the treatment should be repeated regularly at intervals of three or four weeks. At first (if sinuses are present) there may be increased drainage for a short time; later the drainage diminishes steadily, and in the course of from six to twelve months, and occasionally longer, healing may take place (Desjardins, A. U.: The Action of Roentgen Rays on Tuberculous Processes, *Wisconsin M. J.* 34:719 [Oct.] 1935).

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examination of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, October 21, page 1588.

STATE AND TERRITRIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: *Basic Science*. Tucson, Dec. 19. Sec., Dr. Robert L. Nugent, University of Arizona, Tucson.

ARKANSAS: *Medical (Regular)*. Little Rock, Nov. 9-10. Sec., Dr. D. L. Owens, Harrison. *Medical (Eclectic)*. Little Rock, Nov. 9-10. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California). San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: *Medical (Regular)*. Examination. Hartford, Nov. 14-15. *Endorsement*. Hartford, Nov. 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Medical (Homoeopathic)*. Derby, Nov. 14-15. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Examination*. Dover, July 9-11. *Reciprocity*. Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

FLORIDA: Jacksonville, Nov. 13-14. Sec., Dr. William M. Rowlett, Box 786, Tampa.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

KANSAS: Topeka, Dec. 12-13. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Louisville, Dec. 5-7. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

MAINE: Portland, Nov. 14-15. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Regular*. Baltimore, Dec. 12-15. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic*. Baltimore, Dec. 12-13. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Ruslimore, 413-F State House, Boston.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

NEBRASKA: Lincoln, Nov. 24-25. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEVADA: *Written examination and reciprocity with oral examination*. Carson City, Nov. 6. Sec., Dr. John E. Worden, 311 W. Robinson St., Carson City.

NEW HAMPSHIRE: Concord, March 14-15. Sec., Dr. T. P. Burroughs, State House, Concord.

NORTH CAROLINA: *Reciprocity and Endorsement*. Raleigh, Dec. 11. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: Columbus, Dec. 5-7. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: *Basic Science*. Oklahoma City, Nov. 6. Sec. of State, Hon. C. C. Childress, State Capitol, Oklahoma City. *Medical*. Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn, Jr., Frederick.

PENNSYLVANIA: Philadelphia, January. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, Department of Public Instruction, 358 Education Bldg., Harrisburg.

SOUTH CAROLINA: Columbia, Nov. 14. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, Jan. 16-17. Dir., Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TEXAS: Austin, Nov. 20-22. Sec., Dr. T. J. Crowe, 918-19-20 Mercantile Bldg., Dallas.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 13. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WEST VIRGINIA: Fairmont, Nov. 6-8. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Basic Science*. Milwaukee, Dec. 2. Sec., Professor Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical*. Madison, Jan. 9-11. Sec., Dr. E. C. Murphy, 314 E. Grand Ave., Eau Claire.

Tennessee June Examination

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held at Knoxville, Memphis and Nashville, June 15-16, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and eighteen candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Georgetown University School of Medicine.....	(1937)		86.1

North Dakota July Report

Dr. G. M. Williamson, secretary, North Dakota State Board of Medical Examiners, reports the oral and written examination held at Grand Forks, July 4-7, 1939. The examination covered twelve subjects and included ninety questions. An average of 75 per cent was required to pass. Nine candidates were examined, all of whom passed. One physician was licensed by reciprocity and two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School... (1938)	85.4, (1939)		81.3*
Harvard Medical School.....	(1935)		85.2
University of Minnesota.....	(1936)		80.8
University of Oregon.....	(1938)		79.2
Univ. of Western Ontario Medical School... (1936)	75.4, (1938)		78.4
McGill University Faculty of Medicine.....	(1936)		80.8
Regia Università di Napoli Facoltà di Medicina e			
Chirurgia.....	(1936)		80.1

Minnesota June Report

Dr. Julian F. Du Bois, secretary, Minnesota State Board of Medical Examiners, reports the written, oral and practical examination held at Minneapolis, June 20-22, 1939. The examination covered twelve subjects and included sixty written questions. An average of 75 per cent was required to pass. Fifty-six candidates were examined, all of whom passed. Four physicians were licensed by reciprocity and two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Emory University School of Medicine.....	(1937)		85.1
Loyola University School of Medicine.....	(1939)		89.6
Northwestern University Medical School... (1936)	86.5, (1938)		91.2

Book Notices

Menstrual Disorders: Pathology, Diagnosis and Treatment. By C. Frederic Fluhmann, B.A., M.D., C.M., Associate Professor of Obstetrics and Gynecology, Stanford University School of Medicine, San Francisco, California. Cloth. Price, \$5. Pp. 329, with 119 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

This excellent monograph is ineptly named, since the first 152 pages deal with the processes of normal menstruation; viz., the morphologic changes, the physiology and the mechanism of the hormonal controls of the menstrual process. The opening chapter is a splendid historical review of the concepts of menstruation. The morphologic changes and the histopathology are excellently written and particularly well illustrated. The complicated pictures of the hormonal control of menstruation are presented clearly and simply and the references to the literature and bibliography are almost all inclusive. The latter half of the book deals with the pathology of menstruation rather adequately in the light of our present knowledge. It leaves something to be desired, however, in its style, there being considerable overlapping and repetition. These remarks should not detract from the value of the work and the appeal which it should have for the practitioner of medicine. It is by far the best discussion of this problem for the general practitioner that is available today.

Report on Cardiazol Treatment and on the Present Application of Hypoglycemic Shock Treatment in Schizophrenia. By W. Rees Thomas, M.D., F.R.C.P., D.P.M., Medical Senior Commissioner of the Board of Control, and Isabel G. H. Wilson, M.D., M.R.C.P., D.P.M., Medical Commissioner of the Board of Control. Board of Control (England and Wales). Paper. Price, 30 cents. Pp. 70. New York: British Library of Information; London: His Majesty's Stationery Office, 1938.

This is a remarkable book which contains a wealth of accurate data, gathered from dependable and well known authors, a book which bears the backing for accuracy of the English board of control.

The authors tried to be objective as far as is humanly possible and to refrain from personal prejudice. Matter of fact objection is raised to taking very much from the literature of the originators for granted and neglecting to point to the differences which are obvious in the "history" of the development of the treatment as well as the theory. The technic and the results from various authors are stated as completely and efficiently as possible. It seems sometimes that the description of the rather simple technic of the shock produced through metrazol alone is too detailed and elaborately stated. With the same extreme accuracy, the authors describe the technic of the shock produced through insulin treatment, although they had already done so in their first publication. The many variations and possibilities are described and the experiences of the authors are freely mentioned. A wealth of reports from the literature and experiences are presented in such a manner that one interested in a particular question can easily find the details. The book is certainly helpful to any one who needs advice in some particular difficulty.

In the enumerating of the complications and dangers which occur with the use of metrazol alone, the authors are rather too short. They did not cover the numerous publications in America about this subject. In neglecting these and in bringing in just the statement from Meduna, they have made the danger of this treatment appear in an entirely different light from that in which we see it in this country. In reporting the results of treatment by metrazol alone and by insulin alone, they display the same shortcomings. It seems rather strange that the authors,

reporting about American results, neglected the first hand reports, for example the official statistics from the Mental Hygiene Department of the state of New York, published by Superintendent Ross, and used rather the information about the American material given them by Dr. Meduna. They should not have chosen this volunteered information just because it was more accessible. Availability is not sufficient to secure preciseness.

In such a book one expects to find first hand reports on results. By neglecting them the authors create an impression concerning the experience in America, especially with metrazol treatment, entirely opposite to the real situation. The fact that the authors preferred to take their statistics for this country from hearsay instead of using the original official reports from the state of New York, covering a great number of cases, spoils the good record of this book. If they had done it properly it would have shown, as reflected now from the literature and as Sakel pointed out long ago, that the epileptic fit is valuable as symptomatically used by himself but does not have vast importance for a permanent cure.

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1938 with the Comments That Have Appeared in The Journal. Cloth. Price, \$1. Pp. 122. Chicago: American Medical Association, 1939.

This volume tells why the Council on Pharmacy and Chemistry has rejected or why it has not yet accepted the products considered in a given year. In addition it may contain authoritative monographs on the current status of such pharmacologic or therapeutic questions as may have been raised in the course of the Council's deliberations. The last named category is represented in the current volume by the report on the omission from N. N. R. of all creosote and guaiacol compounds. After extensive consideration of the literature and of data furnished by the pharmaceutical firms whose products stood accepted, the Council came to the conclusion that the oral use of such preparations for action on the respiratory passages could be defended only on empirical grounds and that, therefore, they are not a necessary part of the modern therapeutic armamentarium.

Another status report in this volume is that on the use of colloidal sulfur in the treatment of chronic arthritis. After considering the referee's exhaustive report of the literature, the Council concluded that claims for the use of colloidal sulfur in the treatment of chronic arthritis are at present unwarranted and cannot be recognized until satisfactory evidence is available with regard to the following factors: the determination of the types of cases in which it may be used with a fair expectation of benefit; the determination of the chief contraindications; the determination of the optimal dosage; the determination of the best form in which sulfur is to be used, whether as food rich in sulfur, as ordinary sulfur administered orally or as colloidal sulfur for intramuscular or intravenous injection.

Among the preliminary reports in this volume, that on Sulfapyridine, which carries a special article by Dr. Perrin H. Long, a Council member who has been much concerned with the work on this drug, is perhaps of greatest interest. After the Food and Drug Administration had released the drug for the use of physicians early in 1939, the Council accepted various brands for inclusion in New and Nonofficial Remedies and in connection with the published descriptions issued another status report (THE JOURNAL, May 6, 1939, p. 1830) based on a questionnaire sent to men who had been prominent in the experimental use of the drug. This report, no doubt, will appear in the next volume of reprinted Council reports.

The status report on Immune Globulin (Human) appearing in this volume is another example of the procedure just mentioned. It appeared in connection with the published description of accepted brands and followed a preliminary report published in 1935. The longer period of abeyance in which this product was held is noteworthy.

The Council's continuous and, at present, increasing interest in matters of drug nomenclature is attested by the following reports appearing in this volume: Nonproprietary Synonym for Benzedrine and Benzedrine Sulfate (amphetamine and amphetamine sulfate); Sulfapyridine (the nonproprietary name); Questions of nomenclature were involved in the following reports of omission or rejection: Abbott's A-B-D Malt Extract with Cod Liver Oil and Viosterol Omitted from N. N. R.

(unwarranted implied claim for effect of vitamin B complex component); Nupercainal-"Ciba" Not Acceptable for N. N. R. (false implications concerning actual relationship to the accepted Nupercaine); Quinoliv Not Acceptable for N. N. R. (coined proprietary name for unoriginal mixture); Sedormid Not Acceptable for N. N. R. (therapeutically suggestive name); Fru-T-Lax Not Acceptable for N. N. R. (misleading and inadequately descriptive name). Of course, other objectionable features were concerned in the reasons for rejection but the question of nomenclature was given much weight in each consideration.

Attention should be called to the excellent status report on Ergonovine prepared for the Council by Dr. Ralph G. Smith. It will be recalled that Ergonovine is the nonproprietary name adopted by the Council for the new ergot alkaloid which had been given various names by various investigators. Dr. Smith's article is a compendious study of the new drug and its relation to ergot therapy. The Council's name, Ergonovine, appears to be in the process of being generally adopted.

Methoden der Virusforschung. Von Prof. Dr. Henrique da Rocha-Lima, Direktor des Staatl. Biologischen Instituts, São Paulo, Dr. José Reis und Dr. Karl Silberschmidt. Diese Abhandlung erscheint zugleich als Lieferung 480 in Abt. XII, Teil 2 des Abderhaldenschen Handbuchs der biologischen Arbeitsmethoden. Cloth. Price, 24.60 marks. Pp. 384, with 54 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1939.

This volume has an attractive format and contains excellent subject and author indexes. Almost half the text describes the technics of investigations of plant viruses; the remainder gives most of the procedures involved in studies on viruses derived from man and the lower animals, including those of the rickettsial diseases and pleuropneumonia bovum. At the end of each section are numerous references which add definite value. Of the authors, da Rocha-Lima has the respect and esteem of his colleagues for his original contributions to the subject of rickettsiae, particularly those associated with typhus fever, and Reis has studied avian and virus pathology. Silberschmidt is engaged in investigations on plant viruses, especially the study of the immunologic reactions of plants to infection. Within the last eleven years a number of comprehensive treatises dealing with the general aspects of viral agents and the diseases induced by them have been presented to the public. From the first, issued under the editorship of Rivers and of the British Medical Research Council, to those recently published under the direction of Levaditi and of Doerr, methods were described therein only as part of the subjects dealt with. In the present book a special contribution for the advanced student and investigator on virus technology is achieved for the first time. It is to be regretted that its contents are limited. With such limitation, omissions of certain established technics can occur. In the section on inclusion bodies, micro-incineration and the important subject of inclusions produced by nonviral materials are not considered; nor is mentioned, in the section on preparation of materials for animal inoculation, the value of broth as a diluent and suspending fluid or the use of centrifugation for clearing material from concurrent bacteria. Not all the routes of animal inoculation are given. Nor, in the section on determination of size, is the fact stressed that two important considerations are involved in obtaining correct end points: (1) infectivity of the virus in question and (2) its concentration. It would have been desirable, furthermore, to offer centrifugation as a means for recovering virus from neutral serum-virus mixtures and to give explicit procedures of serum-virus protection tests. However, the difficulty should be recognized of preparing a work such as this, on a subject which is so energetically studied, with such great progress. Although other omissions than those mentioned occur, the description of technics in the study of plant viruses, of ultrafiltration, of inclusion bodies and of tissue and embryonated egg cultivation are superior. What is stated in the text (including illustrations) has apparently been taken from original articles—a fact of utmost importance in creating a solid book. Descriptions of many of the most modern developments are included, such as purification of viruses by ultracentrifugation, stream double refraction, the Muench law, the electronmicroscope and light reactions. The present volume should prove of value to phytopathologists who are investigating viruses and should be useful in supplementing existing books on these agents.

William Alanson White: *The Autobiography of a Purpose.* By William A. White, M.D., A.M., Sc.D. With an introduction by Ray Lyman Wilbur. Cloth. Price, \$3. Pp. 293, with portrait. Garden City, New York: Doubleday, Doran & Company, Inc., 1938.

This is a stimulating and inspiring book which succeeds in being true to its subtitle, "The Autobiography of a Purpose". It is written in the first person with engaging candor and frankness. The author has apparently succeeded in taking an objective attitude toward his life, his personality and his purpose. There is no egotism in it nor any self deprecation.

After a preface and introduction in which he gives his reasons for writing the book, he divides his material into three parts. In the first of these he deals with the origin and early expressions of his purpose in life, including chapters on his first fifteen years, his college life, medical school and internship, the beginning of his career in psychiatry at the New York State Hospital at Binghamton and the beginning of his work at St. Elizabeth's Hospital, Washington. Part two deals with the building of St. Elizabeth's Hospital, the development of personnel, factors in administration, his correspondence, consultations, extramural activities, medicolegal experience and teaching. In this part are found chapters on the development of modern knowledge about dementia paralytica and the first use of malaria therapy in the United States. The closing chapter in this part deals with patients he knew and whom he designates characteristically as his friends.

Throughout the book one sees evidence of what must have been the chief characteristic of the author's personality, namely an insatiable interest in human beings and a broad and catholic sympathy for all mankind. His chapter on correspondence shows this universal human sympathy; he never failed to answer letters even from persons of obviously unsound mind. His medicolegal experience is characterized by a constant refusal, after one unsatisfactory incident, to testify for the prosecution on the ground that a doctor's business is to salvage human life and never to assist in its condemnation.

What may be regarded as the key to his life and to his philosophy is found near the end of the book (page 254) in his statement that "ideas are quite as real as chairs and tables and very often at least, if not always, very much more important." He places great emphasis on the modern psychiatric conception of the idea of the totality of the individual as opposed to distinctions between body and mind and he believes that the next great step forward in medicine will be along the line of further acceptance and development and the practical application of this concept.

The book is a valuable contribution both to professional and to popular literature in the field of mental hygiene and psychiatry. No layman can read it without a better understanding of the phenomena of mental disease and a broader and deeper sympathy with those unfortunates commonly known as "crazy people." No doctor can read it without being a better clinician and a wiser physician.

Die Grundlagen unserer Ernährung und unseres Stoffwechsels. Von Emil Abderhalden, o. ö. Professor der Physiologie und der physiologischen Chemie an der Martin Luther-Universität Halle a. S. Fourth edition. Paper. Price, 6 marks. Pp. 193. Berlin: Julius Springer, 1939.

This is an interesting account of the relation between plant and animal nutrition, the nature of the inorganic and organic nutrients, the chemical changes which occur in the intermediary metabolism of individual nutrients, the deficiency diseases, the nutritional significance of the milling of cereals, and the energy requirements of man for work. The author's well known facility as a writer insures an entertaining style. The brevity of the volume necessitated a superficial treatment of the great number of facts mentioned. There is no bibliography. Although the preface is dated January 1939, the book gives the impression that it was written at least two years ago and also that the author is not familiar with recent American researches in nutrition. For example, manganese is mentioned as occurring in the body and nothing is said of its physiologic role, which represents the major discovery of practical importance in poultry production in recent years. There is no mention of the anemia due to cobalt deficiency. Nicotinic acid in relation to pellagra is not mentioned. There are available in English several more timely books on nutrition.

The Diagnosis and Treatment of Diseases of the Thyroid. By James H. Means, M.D., Jackson Professor of Clinical Medicine, Harvard University, and Edward P. Richardson, M.D., John Homans Professor of Surgery, Harvard University, Boston. (Reprinted from Oxford Monographs on Diagnosis and Treatment.) Cloth. Price, \$5. Pp. 367, with 51 illustrations. New York, Toronto & London: Oxford University Press, 1938.

This volume is a series of monographs, each covering a particular phase of thyroid disease and each complete in itself. From the nature of this compilation there is much overlapping and repetition of material. As a whole, the book has given in an interesting manner a true description of goiter throughout the ages. The historical side of goiter and the part that each man has played in the development of our present knowledge is given in detail. The monograph on exophthalmic goiter is thorough. Every theory of the cause is described and criticized; every diagnostic measure is explained and evaluated; a rational understanding of the probable causes and principles of treatment is achieved. Detailed case histories of hospital patients, covering twenty-three years, are given to contrast the diagnosis and treatment at different periods. The book gives little space to cretinism and congenital hypothyroidism, which in some sections of the country are of greater importance than is indicated. These monographs were copyrighted in 1929 and few references to work done in the past ten years have been added.

Über die Wirkung von Erhöhung der Körpertemperatur auf den Kreislauf: Experimentelle Untersuchungen über die Kreislaufverhältnisse bei Erwärmung von Kaninchen mit besonderer Berücksichtigung der Blutdruckregulation. Inauguraldissertation. Von Rumar Brenning. Paper. Pp. 147, with 37 illustrations; Appendix, pp. 47. Uppsala: Almqvist & Wiksells Boktryckeri-A.-B., 1938.

This monograph reports numerous animal experiments, largely with rabbits, on the relationships and mechanisms of circulatory changes associated with elevated body temperatures. There are included many graphs and tabulations. The citations in the literature are more international than is usual with continental publications. Brenning seems to have evolved a rather complex and quite theoretical concept as to the mechanisms involved. The experimental data do not by any means prove his contentions; they merely suggest that his may be one of several possible theories to cover the facts. The factual portion of the work represents extensive and painstakingly careful studies. The monograph will be of special interest chiefly to investigators in the physiology of the circulation and thermoregulation. The clinical applications of the contentions are as yet remote.

Zur Epidemiologie der Kinderlähmung: Eine statistische Analyse. Von Birger Jönsson. Aeta Medica Scandinavica, Supplementum XCVIII. Paper. Pp. 193, with 13 illustrations. Stockholm: Esselte Aktiebolag, 1938.

This book contains an analysis of one epidemic of poliomyelitis which occurred during the years 1935-1937. They had 266 cases of paralysis, sixty-two abortive cases and 129 suspects. No epidemics had occurred in this area previous to 1935. Jönsson considers that the maximum of dissemination of poliomyelitis lies between the maximum of the intestinal diseases typhoid and dysentery on the one hand and contact diseases such as diphtheria and scarlet fever on the other hand. It was found that the disease did not follow the waterways but was most common in areas with the most crowded population.

Medical Microbiology. By Kenneth L. Burdon, Ph.D., Sc.M., Ph.D., Assistant Professor of Immunology and Bacteriology, Louisiana State University School of Medicine, New Orleans. Cloth. Price, \$4.50. Pp. 763 with 120 illustrations. New York: Macmillan Company, 1939.

This book is a revision and enlargement of the Textbook on Bacteriology by the same author. It was apparently written to suit the requirements of the author in his own classroom. Part I is devoted to the historical aspects and other phases of general bacteriology; part II gives brief instructions for laboratory routine; part III presents sources and modes of infection, with brief instructions for procedures in the operating room and the home; part IV deals with the microbiology of some of the more important communicable diseases. Five appendixes contain instructions for the preparation of culture mediums and stains and procedures for immunologic tests. Without doubt the book is satisfactory to the needs of the author, but the brevity of description in some cases is unfortunate. For instance,

the student is instructed to adjust Endo's medium to pH 7.4, but the method of making such an adjustment is omitted. In the chapter on germicides there are a number of rather broad statements concerning some of the commercial preparations, such as "IysoI is one of the most valuable disinfectants known" and "hexylresorcinol, a compound related chemically to phenol, and marketed in a mixture called S. T. 37, is an effective disinfectant." Phenol coefficients are omitted for all germicides mentioned, as are also the various methods of testing the efficiency of germicides.

Studien über hereditäre, multiple Epiphysenstörungen. Ar Sered Bihäng. Akademisk avhandling, för vinnande av medicine Doktorgrad. Upsala. Paper. Pp. 107, with 94 illustrations. Helsingfors, 1937.

The introduction contains a review of the literature of primary disturbances of ossification. This is detailed, covering general conditions such as achondroplasia and cretinism, to localized aseptic necroses, osteochondritis dissecans, osteochondritis deformans coxa (coxa plana) and kyphosis dorsalis juvenilis. The material of the study consists of hereditary anomalies, and the author describes the occurrence of congenital anomalies in six members of a large family. These anomalies are thoroughly studied and elaborately described. They involve multiple joint epiphyses, but especially the metacarpophalangeal articulations, knees, hips and vertebral bodies. The x-ray appearances, which he divides into two principal types, namely anatomic variations and anomalies on the one hand and destructive lesions similar to the osseous aseptic necroses on the other, are most elaborately presented. There are unfortunately no microscopic investigations to correlate with the clinical and x-ray studies. As a monograph on a rather circumscribed subject, built on a comparatively small clinical material, the book is carefully and painstakingly compiled and an interesting contribution to the rather dark field of primary epiphyseal growth disturbances.

Pulmonary Tuberculosis: A Synopsis. By Jacob Segal, M.D., Physician in Charge of Fordham Hospital Tuberculosis Clinic, New York. Foreword by the late Pol N. Coryllos, M.D., F.A.C.S. Cloth. Price, \$2.75. Pp. 150, with 21 illustrations. New York, Toronto & London: Oxford University Press, 1939.

This is a brief presentation on pulmonary tuberculosis. It contains numerous illustrations, mostly prepared from x-ray films of the chest. Approximately half a page is devoted to the first infection type of tuberculosis and the remainder of the book to reinfection clinical forms of the disease. Various phases of the examination for tuberculosis, such as the tuberculin test, symptoms, physical signs and x-ray films, are outlined. Under treatment such subjects as hygienic regimen, fresh air, diet, drugs and physical therapy are briefly discussed. The discussion of collapse therapy includes artificial pneumothorax, oleothorax, pneumonolysis, phrenicectomy and thoracoplasty. In approximately ten pages prevention is discussed, and considerable emphasis is placed on predisposing or contributing causes of tuberculosis, such as living in poorly ventilated and damp houses.

Heart Patients: Their Study and Care. By S. Calvin Smith, M.D., Sc.D. Cloth. Price, \$2. Pp. 166. Philadelphia: Lea & Febiger, 1939.

The author states that the purpose of this volume is to present with clarity and precision all that is useful in the older teachings on impairment of the heart and all that is practical in the maze of modern methods in investigation of the heart. This book is divided into twenty-two chapters dealing with the history and physical examination and the more important forms of cardiac disability. Chapters are also devoted to treating the heart patient rather than treating the heart, what heart patients wish to know and selecting nurses for heart patients. Many of the chapters fall far short of meeting the author's objective. Moreover, there are a number of statements pertaining to important subjects to which serious objections may be taken. Two examples will suffice. The first of these appears in the first paragraph pertaining to electrocardiography, on page 57: "In either indicting a heart or in establishing its innocence, while the patient furnishes testimony and the physician weighs the evidence, the case must be brought to trial in the court of first appeal—cardiography (electrocardiography). Cardiography is also the court of last resort in a differential diagnosis of heart

conditions." The second appears on page 119 in a discussion of the athlete's heart: "From a circulatory standpoint competitive athletics should absolutely be interdicted at schools and colleges. Struggles for supremacy are crippling to the hearts of youth."

Hereditary and Environmental Factors in the Causation of Manic-Depressive Psychoses and Dementia Praecox. By Horatio M. Pollock, Director of Mental Hygiene Statistics, New York State Department of Mental Hygiene, Benjamin Malzberg, Senior Statistician, New York State Department of Mental Hygiene, and Raymond G. Fuller, Director of Research, New York State Committee on Mental Hygiene of the State Charities Aid Association. Cloth. Price, \$2.50. Pp. 473. Utica, New York: State Hospitals Press, 1939.

This volume represents a study of the prehospital history of patients with manic-depressive psychoses and dementia praecox admitted for the first time to the Utica State Hospital in 1928, 1929 and 1930. There are eight chapters: the first deals with a review of studies of the inheritance of mental disease, the second with family stock of manic-depressive patients, the third with the query "Do mendelian laws apply to the inheritance of manic-depressive psychoses?" the fourth with family stock of dementia praecox patients, the fifth with comparative studies of the prevalence of mental disease among relatives of patients and among the general population, and the sixth and seventh chapters with environmental factors in both manic-depressive psychoses and dementia praecox. The eighth chapter contains a summary and conclusions. There is an excellent bibliography and index. One finds in this book a reasonable discussion of these two most important and common mental diseases. Many of the controversial questions are not answered by the authors, but they plead for more research so that in the end there may be an adequate conception of the causative factors in mental disease.

Elektrodiagnostik. Von Dr. B. Neoussikine und Dr. D. Abramowitzsch. Cloth. Price, 12 Swiss francs. Pp. 242, with 30 illustrations. Berne: Medizinischer Verlag Hans Huber, 1939.

This is a thorough discussion of electrodiagnosis. It is written in simple, clear and concise German. There are six chapters and one appendix with thirty illustrations. The first chapter deals with the principles of galvanic and faradic currents. The second part discusses the methods of electrical testing with both currents and chronaxia. The third and fourth chapters list the results of the electrical tests. Normal and pathologic chronaxia values are given for all muscles as well as the variabilities in complete or partial lesions of nerves. The fifth part deals with the use of electricity in examining sensation and sense organs, as the optic, vestibular and acoustic nerves. The sixth chapter discusses testing of the vegetative nervous system and the spinal reflexes. The appendix includes a brief consideration of the impedance angle, psychogalvanic reflex, electrocardiography, electromyography and electro-encephalography. The book is highly recommended to all neurologists, physiologists and physical therapists.

Intracranial Tumors of Infancy and Childhood. By Percival Bailey, Douglas N. Buchanan and Paul C. Bucy. Cloth. Price, \$5. Pp. 598, with 116 illustrations including 23 plates. Chicago: University of Chicago Press, 1939.

This is a needed and desirable monograph. It is the result of a study of an unselected series of 100 consecutive cases from infancy to the sixteenth birthday. All the cases were verified either by study of specimens removed at operation or at necropsy. It consists of fifteen chapters, a bibliography of 483 references, an author and subject index and excellent illustrations of gross specimens, ventriculographic studies and patients. Ependymomas, malignant and benign tumors of the cerebellum, gliomas of the brain stem, optic chiasm and hypothalamus, tumors of the cerebral hemispheres, craniopharyngiomas, tumors of the pineal body and miscellaneous tumors are discussed in detail. There are chapters on general pathology, symptomatology, differential diagnosis and technic and the results of treatment. There are excellent microscopic sections of the various tumors. The book should be read by every neurologist, neurosurgeon and neuropathologist because it will prove to be an excellent reference. It contains so much valuable information, suggestions and points that studying it is the only way to appreciate it.

Blood Group Tests as Evidence of Non-Paternity in Illegitimacy Cases. By Clyde E. Keeler, B.S., M.A., M.S., Instructor in the Howe Laboratory of the Harvard Medical School, Boston. Paper. No pagination. Boston: Robert C. True, Massachusetts Society for the Prevention of Cruelty to Children, 1939.

In this small pamphlet the principles underlying the application of the Landsteiner blood groups and M-N types in disputed parentage are outlined briefly and in elementary fashion. This will serve as an easy introduction to the subject. Unfortunately there are a number of mistakes. Thus the author seems to have the impression that the transfusion of blood from an individual of type M into an individual belonging to type N may give rise to iso-antibodies for M, so that subsequent transfusion of type M blood may be dangerous. Actually the formation of immune antibodies for M or N has never been observed, despite the fact that hundreds of thousands of transfusions are given every year.

Chronic Arthritis. By Robert T. Monroe, A.B., M.D., Associate in Medicine, Harvard University, Boston. Edited by Henry A. Christian, A.M., M.D., LL.D., Hersey Professor of the Theory and Practice of Physic, Harvard University, Boston. [Reprinted from Oxford Loose-Leaf Medicine.] Cloth. Price, \$2. Pp. 84. New York, London & Toronto: Oxford University Press, 1939.

The author of this small volume is an internist, and his book reveals a good sound fundamental knowledge of arthritis. Scientific presentation with adherence to facts and absence of enthusiasm and fads in therapy make this volume exceptionally valuable. Nothing new is added and nothing is omitted. It is written in a concise style and no useless material burdens the reader. Chronic arthritis is divided into three types, atrophic, hypertrophic and periarticular. These are discussed separately from the point of view of etiology, pathology, diagnosis and treatment. Here chronic arthritis is presented in complete form, and the student and physician will find the answers to their problems if they can be answered.

Man and His Health: A Guide to Medical and Public Health Exhibits at the New York World's Fair 1939, Together with Information on the Conservation of Health and the Preservation of Life. Published for the American Museum of Health, Inc. Boards. Price, 50 cents. Pp. 96, with illustrations. New York: Exposition Pub'ns., Inc., 1939.

This is a brief description, with illustrations, of the exhibits in the Hall of Medicine and Public Health at the New York World's Fair. In the Hall of Man is presented a large amount of material on anatomy and physiology from the Oberlander Trust. In the Hall of Medical Science there are twenty-eight exhibits, presented by various scientific and commercial organizations. Brief mention is made of health exhibits found in other parts of the fair, such as the Federal Building and various state and foreign buildings.

A Textbook of Clinical Neurology with an Introduction to the History of Neurology. By Israel S. Wechsler, M.D., Professor of Clinical Neurology, Columbia University, New York. Fourth edition. Cloth. Price, \$7. Pp. 844, with 162 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

This edition contains many additions as well as an introduction to the history of neurology. The latter is a valuable adjunct. Neuritis is regarded as a neuropathy, in a rewritten chapter. The olfactory tests of Elsberg, the carotid sinus syndrome, petrositis, the premotor syndrome and electro-encephalography are included in this edition. There are five parts, on method of examination, the spinal cord, the peripheral nerves, the brain and the neuroses. This book is highly recommended to students and general practitioners.

Pye's Surgical Handicraft: A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of House Surgeons and of Surgical Dressers. Edited by Hamilton Bailey, F.R.C.S., Surgeon, Royal Northern Hospital, London. Eleventh edition. Cloth. Price, \$6. Pp. 512, with 362 illustrations. Baltimore: William Wood & Company, 1939.

The author has brought down to date one of the most complete single volumes on general surgery and has presented it as a guide to house surgeons. Each subject is dealt with in a concise but thorough manner which makes it enjoyable. The chapter on pulmonary complications is especially well presented. Each procedure discussed in a given technic is presented in detail, so that one unfamiliar with the technic can easily follow the steps.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Indorsement of Licenses of Foreign Licentiates; Board's Right to Require Examination of All Foreign Applicants.—The Education Law of New York authorizes the board of regents to indorse a license issued by a legally constituted board of examiners in any other state or country on satisfactory evidence that the requirements for the issuance of such license were "substantially the equivalent" of the requirements in force in New York when such license was issued and that the applicant has been in the lawful and reputable practice of his profession for a period of not less than five years prior to his making application for such indorsement. When the evidence presented is not satisfyingly sufficient to warrant the indorsement of such license, the board is authorized to require that the candidate for indorsement shall pass such subjects of the licensing examination specified by statute or regents' rule as should be required of the candidate to establish his worthiness to receive such indorsement.

Sept. 21, 1936, the Board of Regents of New York adopted the following rule:

"That on applications filed after October 15, 1936, no license issued by a legally constituted board of examiners in any foreign country shall be indorsed pursuant to the provisions of Section 51 of the Education Law, unless the applicant shall pass the licensing examination prescribed by law or Regents rule."

The petitioners in these cases had licenses authorizing them to practice medicine in Germany. In 1937 they applied for and passed in the state of New York the examination in English required of foreign applicants. Both then applied for admission to the January 1938 medical licensing examination, one petitioner reserving any rights he might possess under the New York laws regulating the practice of medicine, but both failed to pass the examination. The petitioners then applied to the board of regents for an indorsement of their German licenses, the board denied the request and the petitioners, in a proceeding instituted in the supreme court of New York, special term, Albany County, sought to compel the board to act favorably on their applications. They contended that the board's rule, promulgated in 1936 and requiring examinations of all foreign applicants, was invalid because the law required an examination of a foreign licentiate only when the evidence of his qualifications was not satisfyingly sufficient and that the evidence of their qualification was sufficient to entitle them to an indorsement of their German licenses.

In the opinion of the court, the rule adopted by the board, however well intentioned, directly contravened the statute. The latter authorizes the indorsement of a foreign license on proof of substantially equivalent requirements and a specified period of practice in the foreign country. The rule permits of no such indorsement but requires every foreign applicant to stand examination. In this respect the board transcended its power; it may not legally set a standard more restrictive than the statute. The exhibits submitted by the petitioners, the court thought, gave prima facie force to their contention that their qualifications were sufficient and an order was issued directing the trial of the issue as to whether the petitioners had actually produced evidence satisfyingly sufficient to entitle them to indorsement of their licenses. From this order the board appealed to the supreme court of New York, appellate division, third department.

As viewed by the appellate division, the sole issue to be determined was not whether the board had exceeded its powers in promulgating the rule in question but whether or not the action of the board in denying the petitioners' applications for indorsements of their foreign licenses was arbitrary, unfair, or capricious. The record before the court did not convince it that the board had rejected the petitioners' applications because of the rule adopted in 1936 but because it had appraised the

evidence of qualifications submitted by the petitioners and had found it wanting. The obvious purpose of the statute, the court said, was to permit the board to indorse a license issued by the licensing board of another state or country in those cases in which the applicant is unable to meet the letter of the requirements of the New York statute but possesses essentially the same or equivalent qualifications. The power granted to the board is a limited one, remedial in its nature, and must be exercised with caution and with due regard to the statutes regulating the practice of medicine in New York. The board may not through the exercise of the power granted by the law indiscriminately indorse foreign medical licenses. Before it may legally indorse such a license it should be satisfied that the applicant has met substantially all requirements. If it errs at all, it should be on the side of the protection of the public from unworthy and inefficient practitioners.

The burden of proving his qualifications is on the applicant. He must not only prove that he graduated from certain institutions but he must also prove to the satisfaction of the board that these institutions are substantially the equivalent of the New York schools. He must not only prove that he has a foreign license but he must also prove to the satisfaction of the board that the requirements for that license were substantially the same as in New York. The petitioners failed to offer such proof. In the Erlanger petition, it was asserted that he began the study of medicine in 1912 and continued it at various German universities until October 1914. It was alleged that he continued his studies after the war and received his diploma and German medical license in July 1922. In the Levi petition, it was alleged that at the beginning of the World War he had completed sufficient medical courses in German universities to serve as an assistant physician and that he did serve as such in various hospitals until the end of the war and that he received his medical license on June 10, 1919. None of the institutions from which the petitioners graduated, the court pointed out, had ever been registered by the board or by the department of education as maintaining proper medical standards. In neither petition was there any allegation that the German standards at the time the petitioners received their licenses were substantially the same as those existing in the state of New York. There was no proof whatever as to the equality of the German institutions, including faculty, length of courses of study, curriculum or equipment. There was no proof that the petitioners ever passed an examination for their licenses as required in New York. What little evidence there was before the board, in the opinion of the court, indicated that the standard of the German schools was lower than the standards in New York and that the requirements for a German license were far from being essentially the same as those in New York.

The petitioners asserted that many other German physicians had been admitted to practice medicine in New York by the board since 1917 by indorsement of their certificates, but the court thought this point to be without merit. What the board may have done in the past was immaterial; the court was concerned only with its action in the cases before it.

To sustain the contention of the petitioners, the court observed, would mean that any foreigner who can speak our language and who has been licensed to practice in a foreign country and who actually practiced there for a period of five years could, on the moment of his arrival at the port of New York, demand the issuance of a license to him to practice his profession in the state. The legislature never had any such intention. Our own citizens, the court pointed out, must pursue a rigorous course of study and supply evidence of good character in order to practice medicine and yet, if the petitioners were correct, any foreigner who was authorized to practice medicine in his native land could come into the state of New York and be immune from such requirements. There was not the slightest bit of proof before the court to indicate that the action of the board of regents constituted an unlawful and arbitrary exercise of power. The orders of the trial court directing the trial of the issue as to whether the petitioners produced evidence satisfyingly sufficient to come within the statute were therefore reversed.

Petitioner Levi then appealed to the Court of Appeals of New York, which in a memorandum decision affirmed the judgment of the appellate division.—*Levi v. Regents of the University of State of New York et al.*; *Erlanger v. Samc*, 8 N. Y. S. (2d) 19; 10 N. Y. S. (2d) 1013; 22 N. E. (2d) 178.

Narcotic Drug Act (Illinois): Information Must Allege Marihuana Is Cannabis Within Meaning of Statute; Court Will Not Take Judicial Notice of Its Composition.—The defendant was convicted in the municipal court of Chicago on an information charging the unlawful possession of a habit-forming drug; to wit, marihuana. The conviction was upheld by the appellate court for the first district and the defendant thereupon appealed to the Supreme Court of Illinois. In the trial court, in the appellate court and in the Supreme Court the defendant contended that the information under which she was convicted failed to charge any criminal offense.

The narcotic drug act of Illinois, 1935, Ill. Rev. Stat. 1937, Ch. 38, makes it unlawful for any person to possess any narcotic drug except as authorized by the act. It defines the term "narcotic drugs" as including cannabis. The term "cannabis" is defined so as to include "the following substances under whatever names they may be designated: (a) The dried flowering or fruiting tops of the pistillate plant *Cannabis Sativa* L., [Linné] from which the resin has not been extracted, (b) the resin extracted from such tops, and (c) every compound, manufacture, salt, derivative, mixture, or preparation of such resin, or of such tops from which the resin has not been extracted." The act makes no specific reference to "marihuana." The prosecution claimed, however, that the word "marihuana" is defined in all standard dictionaries as a narcotic drug of the cannabis family, that it is so well known that the court should take judicial notice of its meaning and that marihuana is therefore included in the narcotic drug act of 1935.

It is to be observed, commented the court, that while the word "marihuana" was included in the narcotic drug act of 1931, it is not in the act of 1935 under which this prosecution was brought. The narcotic drugs embraced in the act of 1935 are specifically defined in it. Even if it is conceded that marihuana is *Cannabis sativa* L., it is obvious that, if the possession of marihuana constitutes an offense under the act, it must be charged that the marihuana alleged to have been unlawfully possessed was from the dried flowering or fruiting tops of the plant named in the act and that the resin had not been extracted. The possession of marihuana is not a criminal offense unless it is of the specific quality and kind defined in the statute. No charge that the marihuana possessed by the defendant in this case was of that specific quality and kind is contained in the information. The information, therefore, did not charge the defendant with any offense known to the law.

The judgment of the courts below were reversed by the Supreme Court and the cause remanded with directions to proceed in accordance with this decision.—*People v. Sowerd* (Ill.), 18 N. E. (2d) 176.

Dental Practice Acts: Validity of Provisions Authorizing Revocation of License for Advertising.—The New Jersey dental practice act authorizes the revocation of the license of any dentist who advertises in any manner his product or the price or charge to be made or the character or durability of his works or products. On proof that Levine had transgressed the statute in this respect the New Jersey State Board of Registration and Examination in Dentistry revoked his license to practice dentistry. Levine then instituted certiorari proceedings before the supreme court of New Jersey. He contended that the provision of the dental practice act just cited is an improper exercise of the police power of the state and is unconstitutional; that it erects a wall of silence behind which monopoly and high prices could flourish, and that the advertisement that he had published respecting the prices charged by him for dental work and the character and durability of his work was true, and, finally, that the provision referred to interferes with his right of free speech in the conduct of his business.

On the authority of *Semler v. Oregon State Board of Dental Examiners*, 294 U. S. 608, 55 S. Ct. 570, 79 L. Ed. 1086, in which the Supreme Court of the United States upheld the constitutionality of a provision of the Oregon dental practice act

authorizing the revocation of the license of a dentist for advertising prices for professional services, the supreme court of New Jersey thought that it was clear that the legislature in authorizing the revocation or suspension for this sort of advertising adopted a measure necessary to protect the public from the wiles and artifices of the charlatan. The truth or falsity of the dentist's assertions, said the court, is of no importance. It is possible that everything that a dentist may say in an advertisement is the literal truth, but if this sort of advertising affords the unscrupulous practitioner an opportunity to practice a deception on his patients, then there is reason why the legislature should authorize the suspension or revocation of the licenses of those who so advertise. The issue before the state board in suspending Levine's license on the charges made was simply whether he had resorted to the prohibited practices, and it was not necessary for it to investigate the truth or falsity of his advertisements, since they admittedly offended against the legislative concept of proper dental practice. To urge that an individual licensed by the state to practice a skilled profession may not be precluded by the state from advertising the price to be charged for his work and the durability thereof is tantamount to urging that the state may not make regulations which will preclude charlatans from enticing the public to their offices by arts which are likely to deceive, and that those engaged in practicing a profession requiring skill and knowledge may not be required to conform to a standard of practice which the people by their representatives deem necessary for their protection.

The supreme court, accordingly, in effect, affirmed the order of the board revoking Levine's license.—*Levine v. State Board of Registration and Examination in Dentistry* (N. J.), 1 A. (2d) 876.

Evidence: Admissibility of Expert Testimony Based on Statements Made by Patient to Expert.—On Sept. 24, 1933, the plaintiff jumped from a speeding automobile, fell on a concrete pavement and was knocked unconscious. Twenty-eight days later, on October 22, she was riding as a passenger in the defendant company's street car when it was struck by a train. She sued the defendant company to recover damages for injuries which she claimed she sustained as a result of the street car accident. From a judgment in favor of the plaintiff, the company appealed to the Supreme Court of Missouri, division No. 1.

An expert medical witness for the plaintiff testified that, based on his own examination and on the history of the case as given to him by the plaintiff, the disturbance of function of the plaintiff's bladder which he found at the time of his examination of the plaintiff in June 1934 was due to a spinal concussion which she had received at the time of the street car accident. The witness admitted that, while he had been told by the plaintiff of the prior automobile accident, he had not been informed that after that accident she had remained in a hospital for ten days because of her injuries, that her reflexes were sluggish, that she complained of pain in her abdomen and that she had paralysis of her bladder necessitating catheterization. He stated that from the history which he had obtained from the plaintiff it was his understanding that she had recovered from the injuries she received in the automobile accident and was well when the street car accident occurred.

The testimony of this witness, the Supreme Court held, was not competent evidence and should not have been admitted. It was based on the history of the physical condition of the plaintiff as told to the witness by the plaintiff herself. The plaintiff did not confine her statements to her physical complaints and ailments as of the time of the examination by the witness. She informed him of her alleged recovery from previous injuries which she had sustained, but she did not reveal the physical injuries and complaints she suffered as the result of that accident. A medical expert witness, said the court, may give in evidence his opinion of the condition of a patient based on his examination of the patient or on the patient's statements as to present symptoms or physical condition or on both such examination and statements. He may not, however, base his opinion on the patient's statements as to past physical condition. The admission in evidence by the trial court of the medical expert witness's testimony was reversible error. The judgment of the trial court was reversed and the case remanded for a new trial.—*Berry v. Kansas City Public Service Co. (Mo.)*, 121 S. W. (2d) 825.

Workmen's Compensation Acts: Compensability of Cerebral Thrombosis Due to Exertion.—The claimant, Uditsky, while engaged in grinding and beveling glass in the shop of the defendant, Krakovitz, exerted himself to prevent a slipping heavy piece of glass from falling. As he did so he experienced a sensation "like a fire" in his head and over his face and also numbness of his left hand. Thereafter he was unable to work. Later his left hand and the left side of his body became paralyzed. His condition was diagnosed as polycythemia vera (a condition characterized by an increase in the number of red blood corpuscles) and cerebral thrombosis with hemiplegia. He filed a claim with the workmen's compensation board for compensation under the workmen's compensation act of Pennsylvania. The board denied him compensation for permanent total disability but awarded him compensation for the loss of the use of his left arm. From a judgment of the court of common pleas No. 6, Philadelphia County, affirming the board's award, the defendant appealed to the superior court of Pennsylvania.

The claimant's claim, said the superior court, was supported by the testimony of two physicians that his condition had been caused by the extreme effort he exerted in saving the slipping glass from falling. In the judgment of the court, therefore, the evidence justified the finding of the workmen's compensation board, on which it based its award that the claimant's condition resulted from an accident in the course of his employment. Accordingly, the judgment of the court of common pleas upholding the board's award was affirmed.—*Uditsky v. Krakovitz (Pa.)*, 2 A. (2d) 525.

Evidence: Testimony of X-Ray Technician in Interpreting Roentgenograms Admissible.—In a personal injury suit a witness was shown to be in charge of the x-ray and laboratory department of a certain hospital "as an x-ray technician who reads and interprets x-rays for the medical staff of that institution" and to have had fifteen years of experience in reading and interpreting roentgenograms. The trial court then permitted the witness to testify that certain roentgenograms disclosed fractures of the vertebrae of the subject but refused to permit the witness "to express an opinion as to whether the fractures were due to trauma or injury." On an appeal to the Supreme Court of Mississippi, division B, it was contended that the testimony of this witness was not competent because he was not a physician and surgeon and because he had never taken a course in anatomy. The witness, said the Supreme Court, was competent to testify as to what the roentgenograms disclosed because his training and experience should have qualified him so to testify. The fact that a witness is a physician and surgeon would not be the best test of competency in this regard, since it is conceded that many medical practitioners are unable to read and interpret roentgenograms. The experience of an x-ray technician in observing the effect of known fractures, as reflected in the pictures thereof, over a period of years, should peculiarly qualify him to state the facts thereby disclosed, although he would not be competent to express an opinion as to what caused the condition showed.—*Aponaug Mfg. Co. v. Carroll (Miss.)*, 184 So. 63.

Medical Practice Acts: Chiropractic as the Practice of Medicine.—A complaint was filed in the city magistrates' court of New York, tenth district, Borough of Brooklyn, charging that Zinke, an unlicensed chiropractor, unlawfully engaged in the practice of medicine and unlawfully used a designation tending to imply or designate himself as a practitioner of medicine. The chiropractor moved for a dismissal of the complaint, contending that it did not charge that he held himself out to be able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition.

The court found, however, that there was directly and by inference a holding out by the defendant that he was able to perform one or more of the prohibited acts. He displayed certificates bearing his name as a "Doctor of Chiropractic" and signs bearing his name as a "chiropractor." He also caused himself to be listed in the telephone directory as a chiropractor. These signs and certificates, the court pointed out, were presumptive evidence of a holding out within the meaning of the

medical practice act. The titles "Doctor" and "chiropractor" carried with them definite implication that the possessor of those titles was able to treat bodily conditions. Furthermore, the setup of the defendant's office, attendant, dressing rooms and split-back robes, neurocalometer and articulated table, constituted equipment of one who uses it as preliminary to and in the actual treatment of physical conditions. When the defendant took the histories of his patients and subsequently treated them and accepted compensation, there arose an inference of a holding out.

Furthermore, the court continued, the defendant diagnosed. His history taking, examination with the use of a neurocalometer and his statements as to the causes of conditions of his patients showed that he made a determination which he deemed sufficient for the purpose of treatment. The term diagnosis, in modern terminology, is a "sizing up" or a comprehending of the physical or mental status of a patient. It is the conclusion itself rather than the procedures on which the conclusion is based which constitutes a diagnosis per se. No particular language need be used and no disease need be mentioned, for the diagnostician may make or draw his conclusion in his own way. The defendant also undertook and offered to treat. The definition of the practice of medicine in New York states that the treatment may be by "any means or method." The defendant's method was by manipulation of the spine.

The court expressed itself as not concerned with whether chiropractic treatments are beneficial or injurious. The only question for determination was whether the facts stated in the complaint showed that the defendant had violated the law. The court was of the opinion that they did and the motion to dismiss the complaint was overruled.—*People v. Zinke (N. Y.)*, 7 N. Y. S. (2d) 941.

Life Insurance: Admissibility of Hospital Records in Evidence.—A Pennsylvania statute prohibits physicians from divulging in civil cases communications made to them by their patients which tend to blacken the character of the patient. In an action on a life insurance policy, the superior court of Pennsylvania held that hospital records, showing that the insured had been treated for chronic alcoholism and delirium tremens, were not inadmissible under this statute. The proscription is restricted to "communications" made by the patient to the physician which tend "to blacken his character." It does not extend to information obtained by the physician from his personal examination. In the judgment of the court, the evidence objected to was either not a "communication" made by a patient to his physician or it did not tend to "blacken" the patient's character.—*Soltaniuk v. Metropolitan Life Ins. Co. (Pa.)* 2 A. (2d) 501.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Blue Nevus, Moles and Melanomas.—Montgomery and Kahler state that the blue nevus has been confused with the Mongolian spot. The latter is usually a solitary plaque from 2 to 12 cm. in diameter occurring on the back, usually near the sacrum. It may be brown rather than blue. It is seen most frequently in the Mongolian race but also occurs in the Caucasian. The pigmented area is poorly defined; it is not elevated or indurated. It is usually present at birth and, as a rule, disappears within the first few years. Occasionally multiple plaques are seen scattered over the body and solitary Mongolian spots have been described elsewhere than on the back. The cells in the Mongolian spot are histologically nearly identical in appearance with the blue nevus cells but are relatively few in number and occur singly rather than in clumps or in masses. There is no disturbance in the normal architecture of the connective tissue and elastic tissue fibers. The blue nevus occurring in infancy or early childhood also must be differentiated from ordinary pigmented nevi, dermatofibroma with hemorrhage (histiocytoma), small deeply situated hemangioma and finally malignant melanoma. The blue to blue-gray usually distinguishes the blue nevus, on clinical grounds alone, from the ordinary brown to brownish-black pigmented nevus. In typical cases the nevus cells in the two conditions present entirely different morphologic features. Dermatofibroma is occasionally blue, especially when deposits of hemosiderin are to be found histologically. A few chromatophores laden with pigment may be seen, but no elongated fusiform melanoblasts (blue nevus cells) are present. A small deep hemangioma may be blue, but it is soft to palpation and blood is obtained on puncture of the lesion. In a few cases blue nevus may simulate the steel blue color of an early malignant melanom-epithelioma in which radiating lines of pigment in the lymphatics have not yet developed. A wide surgical excision is indicated in these cases. The histologic picture is confusing only when the cells of melano-epithelioma elongate into spindle shaped cells frequently containing much pigment. These cells, however, also have an increased amount of cytoplasm and their nuclei are hyperchromatic and frequently contain mitotic figures, three characters which are not seen in blue nevus cells. It is the authors' belief that if blue nevi are looked for they will be found much more frequently than the literature would indicate. Blue nevus rarely shows malignant change. When this occurs it would seem to be that of a relatively slow-growing

melanosarcoma. Like ordinary pigmented nevi, the blue nevus usually runs a benign course and there is no need for surgical excision unless for cosmetic purposes or when the lesion is situated in an area exposed to repeated trauma, friction or irritation.

Seizures in Deteriorated and Nondeteriorated Epilepsy.—Paskind and Brown report studies on the age of onset of the epilepsy in a group of nondeteriorated, well adjusted, non-psychotic nonfeebleminded extramural persons with epilepsy. Their material consists of the records of 368 adult nondeteriorated patients with epilepsy. In order to allow sufficient time for deterioration to occur, no patient was accepted for this study unless seizures were present for at least six years. Patients with defective mental development and with focal signs of neurologic disorder were not accepted for this study. A comparison of the age of onset of these nondeteriorated patients with that of institutional, deteriorated patients revealed that: 1. Fewer nondeteriorated patients have the onset before 5 years of age. 2. Fewer nondeteriorated patients have the onset before 10 years of age. 3. More nondeteriorated patients have the onset after 20 years of age. 4. More nondeteriorated patients have the onset after 40 years of age. It is concluded that deteriorated patients with epilepsy differ from the nondeteriorated ones in that there is a tendency to later onset in the non-deteriorated patients. The material which the authors used for the studies on the frequency of seizures consists of the records of 317 adult nondeteriorated extramural patients with epilepsy. No patient was accepted for this study unless he had had seizures for at least six years. Patients with defective mental development and with focal signs of neurologic disorder were not accepted for this study. The seizures studied were of patients who had had no treatment or only inadequate, irregular treatment. Comparing the frequency of major seizures in their series of nondeteriorated patients with the frequency of such seizures in deteriorated institutional patients, the authors say that in their series 5.7 per cent had grand mal seizures at intervals of less than a day. This ratio is much smaller than that given in other reports, in which comparative figures vary between 10.9 and 20.4 per cent. In 14.5 per cent of the present series of patients, major seizures occurred at intervals of a week or less. This figure again contrasts markedly with other reports in which the comparative figures vary between 18.3 and 56 per cent. In 52.1 per cent of the patients of the present series grand mal seizures occurred at intervals of one month or less. Comparative figures in other statistics are between 54.7 and 90.3 per cent. The percentage of patients in whom the major seizures occurred at intervals of greater than one month was 47.9 in the material investigated. This figure is greater than that given by any other writer. Thus it appears that extramural, nondeteriorated patients have major seizures less frequently than do the deteriorated patients in institutions. A search of the literature revealed only one statistical statement regarding the frequency of petit mal attacks; Gowers stated that in half the cases the attacks occurred daily. In the material analyzed by the authors the frequency of petit mal attacks could

be determined in 137 cases. They occurred at intervals not exceeding one day in 21.2 per cent of cases. In the conclusion the authors emphasize once more that in noninstitutional, non-deteriorated patients with epilepsy, seizures are significantly less frequent than they are in deteriorated institutional patients.

Differential Diagnosis of Exophthalmic Goiter.—King and Sohval say that whereas typical cases of exophthalmic goiter present no difficulty in the diagnosis, borderline cases, in which the symptomatology is not so clearly delineated, are not so easy to differentiate on clinical grounds. Efforts have been made by previous workers to find some objective laboratory tests which would simplify the differentiation of such conditions as autonomic imbalance, the menopause, hypertension and non-toxic goiter from true exophthalmic goiter. In this study King and Sohval investigated the comparative value of the determination of the basal metabolic rate, the creatine tolerance and the velocity of the blood flow. These tests were made in a group of eighty-seven cases comprising seventeen of exophthalmic goiter and seventy of borderline and allied disorders. Regarding their experience with the determination of the basal metabolic rate, the authors say that the basal metabolic rate is uniformly elevated in exophthalmic goiter and is reduced by the administration of iodine and by subtotal thyroidectomy. In the borderline and allied cases, initial determinations are frequently elevated and misleading. At times repeated determinations are necessary before the true basal rate is obtained. Especially does this hold in cases of autonomic imbalance. In some instances the authors succeeded in obtaining an accurate (normal) figure only after hospitalization. An elevated figure obtained in a random determination of the basal metabolism of an ambulatory patient is wholly unreliable. The determination of the velocity of blood flow as measured by the saccharin method in terms of arm to tongue circulation time has not been used as an adjuvant in the clinical diagnosis of exophthalmic goiter. Since, according to investigations, the velocity of the blood flow is roughly in direct proportion to the basal metabolic rate, the authors decided to determine it in their cases. They measured the circulation time by the interval elapsing between the injection of saccharin into the antecubital vein and the perception of the sweet taste in the tongue. One hundred and sixty-seven determinations were made in eighty-eight cases. The authors found that the determination of the circulation time fails to afford a laboratory aid in the differential diagnosis between exophthalmic goiter and the borderline cases, since the differences are not clearcut enough and there is considerable overlapping of figures. Their experience with the creatine tolerance test discloses that it is also limited in its usefulness and may give discordant results. Laboratory aids in general are inadequate as absolute criteria in the differential diagnosis between exophthalmic goiter and the borderline cases which simulate it. However, the determination of the basal metabolic rate excels the circulation time test and the creatine tolerance test in usefulness. In the last

analysis, clinical judgment surpasses in value any of these laboratory aids. The latter should assume a secondary role and be employed with distinct knowledge of their limitations and shortcomings.

Upper Small Intestine and Gastric Secretion.—Shay and his associates studied the effect on gastric secretion of neutral fat, fatty acid and soap in the upper intestine, the phase of secretion influenced from the intestine and the relative importance of the psychic and chemical phases of gastric secretion. They selected eight patients with a normal or high gastric acid response to the Ewald meal and with no demonstrable organic gastrointestinal disease. In order to satisfy any questions that might be raised regarding the chemical effect of zwieback and water as the test meal, numerous studies were done with 200 cc. of 2 per cent Liebig's extract as the gastric meal. The change in gastric secretion produced by duodenal stimulation was independent of the type of mouth meal used. After an overnight fast two Rehffuss tubes were introduced into the stomach. One was passed into the duodenum by the usual technic, whereas the other remained in the stomach. When the duodenum was intubated, the positions of the tubes were determined fluoroscopically. The fasting gastric contents were removed and the test meal was administered by mouth. The Ewald meal consisted of 30 Gm. of zwieback and 300 cc. of distilled water at body temperature. Duodenal instillation of the test substances in the separate studies was begun with the mouth meal, except when the effect of a time lapse in their administration was being studied. The effect on gastric secretion of the additional tube through the pylorus was investigated. As previously reported, a tube so placed did not influence gastric emptying; under similar conditions it failed to modify gastric secretion. The studies reported by the authors demonstrated consistent marked depressions of gastric secretion in man when neutral fats, fatty acids and soaps in proper concentrations were instilled into the duodenum simultaneously with the mouth meal. All secretory fractions were involved: acid, chloride and enzymes. This depression of secretion continued for a considerable period after the instillation of the stimulant was stopped. A secondary sharp rise in gastric secretion was nearly always observed after the duodenal stimulating effect was overcome. The authors were unable to confirm the opinion that this secondary rise in secretion is dependent on the formation of soaps in the upper intestine, the action of which is supposed to cause stimulation of gastric secretion. The duodenal instillation of a soap, such as sodium oleate, in proper concentration (15 per cent) produced, just as oil, first depression and then rise in secretion. The authors frequently saw a sharp rise of gastric secretion after the depression stage from agents other than fats. The result obtained with 40 per cent dextrose, used to illustrate the action of agents other than fat or fat derivatives, represents the most striking secondary rise of secretion. Obviously, soap formation is not involved here. By the use of duodenal instillates of different concentrations (2 and 15 per cent sodium oleate) the authors obtained a difference between the thresholds of response of the gastric motor and secretory mechanisms. The motor mechanism appears to have a lower threshold than the secretory. The mechanism of enzyme secretion also appears to be influenced differently from the acid mechanism. This is seen in the almost consistent earlier rise in enzyme concentration after the duodenal stimulant is stopped. The question was raised whether the secondary rise in the gastric secretion, following the secretory depression from the duodenal instillation of oil, might not represent a discharge of secretion stored up during the depression period. The authors believe that the duodenal influence is exerted chiefly, if not entirely, on the psychic phase of gastric secretion and, further, that this phase represents the important one. This is based on the prevention of the stimulation of gastric secretion during insulin hypoglycemia and on the failure of duodenal stimulation to prevent a rise in gastric secretion following histamine injection.

Specific Treatment of Staphylococcal Septicemia.—Julianelle says that the differentiation of staphylococci into types A and B was established primarily by immunologic and chemical differences between the intracellular polysaccharides extracted from the respective organisms and secondarily by the biologic distinction that type A strains are derived from pathogenic conditions while type B strains are apparently saprophytic. Lat

the determination of types was simplified by the mannite fermentation test, which separates type A from type B by the ability of the former to metabolize acid from this sugar. Cutaneous tests indicated that, while the polysaccharide of type B is cutaneously inert, the similar preparation from type A elicits reactions in approximately 12 per cent of normal infants and children and 70 per cent of normal adults. An additional observation of greater importance was that, irrespective of skin reactivity, precipitins for the specific carbohydrate were demonstrable in the scrums of only those patients suffering from severe, prolonged, generalized infection and, indeed, only in those eventually recovering from the infection, so that the appearance of precipitating antibodies in the serums of patients has been accepted as a sign of favorable prognosis. Reflecting on the significance of the presence of precipitins only in the serums of patients recovering from critical infection, it was proposed to treat patients who had staphylococcic septicemia with antiserum containing a high titer of the precipitins capable of reacting with the specific carbohydrates. All the antisera used in this study were prepared from rabbits but it is probable that the antisera from other animals may be equally effective. After describing the preparation and administration of antisera, the author describes his clinical observations. Seventeen patients suffering with staphylococcic septicemia secondary to a primary lesion yielded on culture staphylococci belonging to type A and capable of fermenting mannite. All the patients were treated with type A antiserum prepared in rabbits and were given in addition whatever supplementary measures were indicated; such as surgical drainage and blood transfusions. The untoward reactions ascribable to the serum were mild, and in four cases the treatment was followed by serum sickness. The cutaneous reaction to the carbohydrate of type A is suggested as an index of sufficient treatment. Of the seventeen patients treated with type A antiserum, seven recovered and ten died. Of the ten patients dying, four died before the end of the first day of treatment, four had developed sterile blood cultures (and of these, three died of other causes) and two died with typical signs of staphylococcic infection. Exclusive of the four patients who succumbed within the first day, type A antiserum apparently sterilized the blood in eleven of thirteen cases.

- "Cardiac Cirrhosis" of Liver.—In examining 2,000 consecutive necropsy protocols, Katzin and his collaborators found that 286 of the deaths were due to congestive cardiac failure. Increased hepatic fibrous tissue was found in one third of these cases and this was approximately three times the incidence found in the remaining 1,714 cases in which congestive failure was absent. The incidence of fibrosis in cases of chronic passive congestion increased with the duration of congestive failure, and the more severe grades were found in cases in which the illness

was of longest duration. The causal significance of chronic passive congestion in the production of hepatic fibrosis was emphasized by the increasing incidence and severity of the fibrosis with increasing duration of congestive cardiac failure. The only type of increase of fibrous tissue peculiar to this group of cases of cardiac decompensation was central fibrosis, for, with a single exception, no instance of central fibrosis was found among the 1,714 cases in which necropsy failed to disclose congestive failure. Portal fibrosis also was found in a larger percentage of such cases than in cases in which chronic passive congestion was absent. This suggests that chronic passive congestion with resulting anoxemia, by increasing the susceptibility of the hepatic tissue, is also a contributing factor to fibrosis in the portal areas.

Phosphatase Activity in Chronic Arthritis.—Steinberg and Suter determined the phosphatase content of the serum of forty-four patients with atrophic arthritis, eight with hypertrophic arthritis, five with mixed atrophic and hypertrophic arthritis, five with osteitis deformans and six healthy persons. In the only case of arthritis in which the value for serum phosphatase was above 4.2 units it was later proved that malignant tumor of the prostate gland was present, with secondary involvement of osseous and pulmonary tissue. An increase of serum phosphatase in this type of malignant disease has been described by Gutman and his co-workers. Determination of the phosphatase content of the serum in cases of chronic atrophic and hypertrophic arthritis is therefore important in the differential diagnosis. A normal value for serum phosphatase is characteristic of chronic atrophic or hypertrophic arthritis; an abnormal value suggests the possibility of a complicating condition or an erroneous diagnosis of this condition. Determinations of the phosphatase content of the serum should be made a routine procedure in the study of diseases of the bones and joints.

Intracerebral Carcinomatous Metastases.—Hare and Schwarz describe the clinical features of 100 cases of intracerebral carcinomatous metastases and the pathologic features in thirty-four of these cases in which necropsy was performed. The study is limited to cases in which the tumor has spread, presumably by way of the blood stream, to involve the parenchyma of the brain. The authors' conclusions are that: 1. Bronchogenic and mammary carcinoma commonly metastasize to the brain. 2. The primary carcinoma in cases of cerebral metastasis is most commonly in the lung or breast; sixty-five of the 100 primary tumors were so located. 3. A bronchogenic carcinoma often manifests its effects by cerebral metastasis before there are any pulmonary signs. 4. Carcinoma with cerebral metastases is not uncommon in persons less than 40 years of age. This occurred in twenty-seven of the 100 cases. 5. The disease occurs predominantly in male patients in the ratio of 3.2:1, provided the cases of primary carcinoma of the breast are excluded. 6. Symptoms of metastasis are usually of short duration before the patient becomes seriously ill. 7. The onset of intracranial symptoms occurred suddenly in thirty-six cases. 8. Patients with metastatic cerebral tumor do not tolerate surgical procedures well. The average duration of life from the time of the first neurologic symptom until death was 3.6 months for the thirty-two persons who died while under the authors' care. The survival period was much shorter for those who were operated on. 9. Mental alterations of varying degree were present in 50 per cent of the patients studied. 10. Severe headache may be a prominent symptom. It may or may not be associated with papilledema. 11. Signs of chronic debilitating disease may be absent. They were lacking in 40 per cent of the cases. 12. Abnormality of the spinal fluid occurred in 70 per cent of the cases in which it was examined. 13. X-ray evidence of erosion of the sella turcica may be present. It was not uncommon in spite of the short duration of the cerebral metastases. 14. Encephalographic and clinical studies may localize one of the metastatic masses, which is usually the largest, and may fail to show the presence of other, smaller, nodules. 15. Even after metastasizing to the brain, bronchogenic carcinoma may not appear as such on roentgenograms of the chest. 16. Metastatic cerebral tumors may be single or multiple. Multiple tumors were observed in twenty brains removed at necropsy. 17. In practically all cases of cerebral metastasis there are metastases to other organs. 18. Cerebral disease in addition to the metastases may be present. Such was the case in four of the

present series: cholesteatoma in one and syphilis of the central nervous system in three. 19. Surgical removal of single metastases in a few cases may prolong life for months or even for several years; however, such cases form a small percentage, as most patients die shortly after craniotomy. 20. Subtemporal decompression often relieves the headache and affords great comfort to the patient. 21. When craniotomy is to be performed, x-ray studies of the chest should be made, regardless of the age of the patient.

Atrophic Rhinitis.—Eagle and his associates used estrogens in the treatment of fourteen patients with atrophic rhinitis. Sections of their nasal mucosa were studied before and during or after treatment with regard to specific histologic alterations attributable to the local action of the estrogens. The first biopsy specimen in each case was obtained previous to any treatment and the second one was taken from twenty-seven to 216 days after the first treatments with estrogenic substances were started. No patient complained specifically of deafness and tinnitus. Twenty-two patients started the estrogenic treatment and had the original biopsy but, owing to economic reasons and the distance to the clinic, eight did not return for the second biopsy. The patients irrigated their noses twice daily with physiologic solution of sodium chloride or 1:10,000 solution of potassium permanganate and ten minutes later repeated the irrigation to remove the crusts that had been loosened by the earlier washing. Then 0.5 cc. of estrogenic substance was sprayed into the nose twice daily, giving each patient the equivalent of 1 cc., or 1,000 international units, of estrogen daily. Twenty-one of the twenty-two patients reported clinical benefit and each wished to continue treatment. The patient with stormy menopausal symptoms stated that she was not improved to the slightest degree. Inspection of the nose revealed certain marked diminution or complete eradication of crusts in all fourteen cases in which the study was completed, and in no instance was the odor characteristic of the disease detectable. The only changes noticeable in the mucosa were a slight increase in hyperemia and a smoother surface. Patients complaining of a burning sensation in the scalp and occipital headache were relieved of these symptoms. The authors are unable to state whether the patients' noses were free of crusts because of the more frequent irrigations or because of the estrogenic therapy. The impression was that the surface epithelium and the subepithelial glandular system contained more mucous cells after treatment than before. It appeared that the amounts of squamous and ciliated epithelium and the vascularity, as well as various other features, were not altered. No perfectly consistent change in any one direction existed. Fibrosis was recorded more frequently before than after treatment. The protocol method of analysis suggested increased function of the mucous glands, and the statistical method decreased density of the tunica proper after treatment. It is possible that study of a far larger series of patients might give significance to some of these suggestions. The present observations indicate the absence of obvious morphologic changes.

Larynx in Infantile Beriberi.—Alcantara and deOcampo examined the larynxes of thirty-seven infants from 1 to 9 months of age with infantile beriberi. In eleven the disease was complicated by acute infection of the respiratory tract. Hoarseness

and weakness of the voice, or aphonia, was the most frequent symptom. The final diagnosis of infantile beriberi was given in all these cases by the pediatrician. The laryngeal lesions found were as follows: The five patients with acute cardialgic beriberi, in whom the impairment of voice was slight, showed only slight congestion of the vocal cords, their motility being normal. In the rest, impairment of motion of the vocal cords existed. The right vocal cord was paretic or could not move completely to the median line in four cases, stayed immobile in the middle in nine and assumed a cadaveric position in three. The left vocal cord was paretic in five cases, completely immobile in the median line in nine and cadaveric in one. The vocal cords were bilaterally affected in three cases. In some cases the paretic vocal cord appeared at a lower level than the normal. Twenty-two of a control group of thirty-one children with diseases other than infantile beriberi but with hoarseness as a complaint also, examined laryngoscopically, showed only congestion of the vocal cords, which moved normally. The rest had impairment of movement of the vocal cord, but in almost all of them there was a coexistent pathologic condition which might explain the paresis. In the rare cases in which the impairment of motion seemed to be entirely attributable to the inflammatory congestion of the larynx, the hoarseness and the impaired motility were of short duration in contrast to their long duration in the cases of beriberi. The authors believe that impaired motility of the vocal cords should be added to the already recognized diagnostic factors of infantile beriberi. In cases in which beriberi and acute infection of the respiratory tract coexist, the motility of the cords is of help in determining whether both are present and what degree of deficiency of vitamin B₁ exists in the child. Irritation and then degeneration of the abductor fibers of the vagus nerve followed by similar changes in the other fibers, the tensors and adductors appear to be the clinical facts in the production of the laryngeal lesions. Cardiac enlargement does not seem to have any influence on the degeneration. Clinically and probably pathologically, at least with regard to the laryngeal lesions, there is a close similarity between adult and infantile beriberi.

Constitutional Background of Respiratory Infection.

—Price studied the influence of constitutional factors in infections of the upper part of the respiratory tract by examining two groups of subjects. One of these groups was selected from 754 male and female students at Ursinus College and was composed of young men and women who came from good, solid, substantial, middle class families, representing the average, normal type. The other group was a cross section of the male and female inmates of Pennhurst State School, degenerative types. Members of both these groups live in the same vicinity, the institutions being within 10 miles of each other. Subjects of the degenerative type are more affected by the constitutional factors in their basic background than are those of the other type, who are slightly affected. The difference in the incidence of infection of the upper part of the respiratory tract in the two groups strikingly indicates the variation of the constitutional factor. In an analysis of this factor, the vasomotor reactions in the two groups were compared by studying the dermatographic response. The dermatographic reaction was more definite in the degenerative group. It is pointed out that abnormal vasomotor reactions may be an important element in the mechanism of infection of the upper part of the respiratory tract. Unless the constitutional factors in the case can be changed definitely, treatment will accomplish but little. Physiologic equilibrium should be the goal. If the autonomic system, the endocrine system or the acid-base metabolism is at fault, one must diagnose the condition and attempt to regulate it physiologically.

Incidence of Syphilis in Delaware.—Beck states that 868, or 94.5 per cent, of the students at the University of Delaware were given Kahn and Wassermann tests and only one positive blood reaction was obtained. Other groups (domestics, food handlers, nursery school children and industrial school girls) were also tested and the proportion of positive reactors ranged from 0 to 4.5 per cent in the white persons and from 4.8 to 47.2 per cent in the Negroes. From the figures presented, it is estimated that less than 2 per cent of the white and about 30 per cent of the Negro population of Delaware have syphilis.

Chronic Rheumatic Infection and Mental Illness.—Chronic rheumatic infection might be the etiologic factor in certain cases of long standing mental illness. In the necropsy service of the Central State Hospital of Indianapolis, Bruetsch and Bahr observed that, in some subjects with old rheumatic changes on the heart valves, gross lesions in the form of small or large infarctions were present in the brain and at times in other organs. In most of these instances the clinical record did not give reference to a previous rheumatic infection, and none of the patients had gone through an acute attack of rheumatic fever while an inmate of the institution. Particular attention was given to the presence of rheumatic valvular heart disease in the necropsies of 500 mental patients. Other forms of endocarditis, such as the subacute bacterial form, were ruled out by gross and microscopic examination. The anatomic investigation disclosed chronic rheumatic valvular disease to be present in 4 per cent. Microscopic examination of all the organs of these patients showed that the long-continued rheumatic infection had involved not only the heart but also the brain and other organs, such as the kidneys, spleen and pancreas. The changes in the brain consisted of an obliterating rheumatic endarteritis of small and larger vessels having resulted in gross and microscopic infarctions and in numerous minute areas of incomplete softening (acellular areas). Small connective tissue scars originating from proliferating vessels and extending over several cortical cell layers were frequently observed. Glial nodules were occasionally seen in the cortex and in the white matter. Two patients with a psychosis of short duration had a rheumatic encephalitis. Some of the cases were diagnosed as dementia praecox, others as manic depression or as involutional and senile psychoses. In two cases the diagnosis was psychosis with cerebral arteriosclerosis, because residual signs of a "stroke" were present. If the rheumatic infection produces brain lesions in childhood, mental deficiency may result.

Endocrine Control of Prostate.—Vidgoff points out that an endocrine relationship is implied because man's sexual activity is supposedly waning when prostatic hypertrophy becomes troublesome. The accidental finding of epithelial metaplasia in the prostate of animals after the injection of theelin has led to the theory of estrogenic dominance in a bisexual organ as the explanation of the clinical picture. The author is not convinced that this is a specific observation because it is well known that estrogenic substance is a general epithelial stimulant. Furthermore, the anatomic evidence does not support this theory. The many reports of remarkable relief from the clinical picture with testosterone are not convincing. In animals, testosterone causes a hypertrophy of the prostate. The clinical experimental work has been insufficiently controlled. The beneficial effects obtained by the use of the testosterone in prostatic hypertrophy is probably due to the effect on the congestion surrounding the adenoma. For the same reason, prostatic hypertrophy in the human being is capable of undergoing spontaneous amelioration. There is evidence to show that the testis elaborates a substance which has an inhibitory effect on the prostate. This inhibitory substance has not been isolated as yet, but work going on at present shows promising results. Much experimental work on the problem, rigidly controlled, is necessary.

Heredity in Jewish Diabetic Patients.—Rudy and Keeler collected data on the importance of heredity as an etiologic factor in diabetes mellitus in the families of 1,037 Jewish patients. Among 1,000 successive nondiabetic patients admitted to the

Beth Israel Hospital, sixty-three reported one or more members of their families as having had diabetes. The disease was at least four times as frequent in the families of the 1,037 diabetic subjects. According to Cammidge it is even more than eleven times as frequent. From the data of their hospital records the authors found 29.1 per cent with one or more diabetic individuals in their families. Interviews with 246 Jewish diabetic patients revealed a higher proportion of positive family histories, eighty-seven (35.3 per cent). Of 302 patients with a positive family history of diabetes, 164 (15.8 per cent) gave a hereditary history and 138 (13.3 per cent) only a familial history. Adult Jewish diabetic patients (aged 20 or more) show 28.6 per cent diabetic heredity: 15.3 per cent hereditary and 13.3 per cent familial. Jewish patients show a higher frequency of the familial type of diabetic heredity regardless of age. The ratio of women to men is nearly 2:1. Of twenty married couples with diabetes, from the ages of 48 to 77, two couples had no children, and six of the remaining eighteen had one diabetic child each. In the majority of the Jewish men and women diabetes developed between the ages of 50 and 54, the same age Joslin found for all his men and women patients. A study of the A and B blood groups and the M and N blood types has been carried out in some diabetic patients in order to determine whether there is any relation between the diabetic constitution and the known blood characters. The data are not considered conclusive but it may be said that the distribution of the blood types M and N and the blood groups A and B in diabetic patients shows no striking difference from that in nondiabetic patients already reported in the literature.

Heart Block from Thyroid Extract.—Aisner and Dorsey cite a case of complete heart block following an overdose of thyroid extract taken for obesity. A review of the literature since 1882 shows ten cases of complete heart block developing during the course of true hyperthyroidism but no cases in which the block was induced by the administration of thyroid extract. The transient nature of the heart block in the case reported suggests that the disturbance may be a function of reversible chemical changes in the myocardium rather than of morphologic alterations. The case illustrates what may be expected from the uncontrolled use of thyroid extract in the treatment of obesity.

Flask as Aid to Tactile Fremitus.—Just as the stethoscope has been an improvement over direct auscultation, Reich found that a 100 cc. Erlenmeyer flask was capable of increasing and localizing tactile fremitus. The flask conveyed the vocal vibrations from the wall of the chest to the hand in a most satisfactory manner. This was found to be especially suitable because of the thinness of the glass, the smooth, small localizing mouth flaring out at the base to cover a large area of palmar tactile endings. Less satisfactory was a 75 watt electric light bulb. The flask or bulb is applied lightly to the various regions of the wall of the chest with gentle pressure on the base with the open palm (ulnar side of the hand) or fingertips, with the patient repeating a short phrase or words or numbers. The usual variations exist; increase or decrease of tactile fremitus in pathologic conditions has the

same interpretation as that done with the hands only. The flask can prove useful in helping to localize small or early lesions of the lungs.

Hematogenic Tuberculosis.—Billard discusses the clinical aspects, pathologic changes and pathogenesis of hematogenic tuberculosis and in summary points out that pulmonary tuberculosis resulting from infection by way of the blood stream produces a clinical entity separate and distinct from the disease acquired by the usual bronchogenic route. The condition may be acute generalized miliary tuberculosis, producing a fulminating fatal condition involving the lungs and other organs in the body, or it may be chronic miliary tuberculosis in which the demonstrable lesion is limited to the lungs, although extrapulmonary foci, especially in the bones, joints and genitourinary tract, may occur without clinical evidence. These pulmonary lesions may be of varying extent, are usually bilateral and have a tendency to symmetry and localization in the apexes and the upper lobes. Symptoms of pulmonary disease may be mild or absent. Chronic hematogenic lesions are produced by single or repeated disseminations of bacilli into the circulation from various sources, as caseating tracheobronchial nodes, the primary pulmonary focus or extrapulmonary foci. They may heal by complete absorption, diffuse, fine fibrosis or dense, discrete calcified deposits. On the other hand, the lesions may run a low grade chronic or subacute course or they may progress and break down, producing bronchogenic dissemination. Foci are created simultaneously in extrapulmonary organs. They may be of the abortive type or they may give rise to chronic low grade infection. In chronic hematogenic tuberculosis, acute fatal dissemination may occur at any time; however, in the majority of cases the course is mildly protracted and patients suffer less than those with bronchogenic infection.

Pulmonary Embolism.—De Takáts and his associates produced experimentally two types of fatal pulmonary embolism: one which plugs the terminal vascular bed and is characterized by cyanosis and dyspnea, and the other which represents an obstruction to the main pulmonary artery and exhibits a syncope attack with pallor and a fall in the blood pressure. The possible mechanisms of death are analyzed. Atropine, papaverine and oxygen are helpful in the peripheral type of embolism. Electrocardiograms taken of dogs before and after the production of a massive pulmonary embolism present a picture resembling serious interference with coronary flow. The possible causes of this interference are reflex vagal inhibition of the heart, peripheral vascular collapse arising from pulmonary hypertension through the depressor nerve and right acute ventricular failure. In the authors' series of 100 cases of pulmonary embolism there were eighty-seven deaths and thirteen survivors. Of the fatal cases, death occurred in less than 10 per cent within the first ten minutes, thus allowing time for emergency measures. On the basis of their experiments they recommend a combination of atropine and papaverine to counteract the radiation of autonomic reflexes, which originate in

the affected lung. Oxygen is obviously useful in the peripheral type of embolism, in which vasomotor collapse is absent but cyanosis predominates. The commonly employed drugs epinephrine, neosynephrine, digitalis and strophanthin are discussed but not recommended. As manifest thrombosis of the veins of the pelvis and lower extremities is comparatively rarely seen in patients with massive pulmonary embolism and heparinization of a large number of postoperative cases is yet impossible, early and active interference with the autonomic reflexes may be the only available life-saving measure.

Uterine Bleeding and Granulosa Cell Tumors.—Seegar and Jones state that abnormal uterine bleeding in association with ovarian tumors has been analyzed as to cause and frequency in a group of 376 cases. The mechanism responsible for the abnormalities in menstruation varies with the pathologic type of ovarian tumor. The highest occurrence of abnormal uterine bleeding was found in association with the tumors of granulosa derivation. In thirty-five papillary granulosa cell tumors, 45 per cent were associated with abnormal uterine bleeding. Of the fifty-nine solid granulosa cell tumors, 62 per cent were found to be associated with menstrual abnormalities. In both groups in which endometrium was available, endometrial hyperplasia was the direct cause of the uterine bleeding. The hyperplasia is presumably produced by the estrogenic secretion of the tumor itself. A more careful study of the uterine endometrium, together with endocrine studies on the blood and urine of patients with ovarian neoplasms, will render valuable assistance in the correct classification of ovarian tumors.

Malignant Tumors of Small Intestine.—Medinger gives the incidence of malignant tumors of the small intestine found in the pathologic material of the New England Deaconess and Palmer Memorial Hospitals during a period of twelve years. In a total of 1,456 postmortem examinations, malignant conditions were found in 63 per cent. There were approximately 41,000 surgical specimens and in 20 per cent of these the primary diagnosis was malignant growth. A review of the same series shows only ten cases that came to necropsy with malignant tumors of the small intestine, or an incidence for all necropsies of 0.69 per cent. The surgical material shows twelve cases, an incidence for malignant neoplasms of the small intestine of 0.03 per cent of the total specimens and 0.15 per cent of the total malignant growths removed surgically. Three of these twenty-two tumors were of duodenal origin, twelve jejunal and seven ileac. Sixteen were carcinomas and six sarcomas. The author's analysis of 134 cases of malignant growths of the small intestine, including his own series, shows

malignant tumors of the duodenum and ileum to occur slightly more frequently than malignant tumors of the jejunum. Carcinoma occurs most frequently in the duodenum and jejunum and sarcoma in the ileum. The clinical picture of carcinoma of the small intestine is variable. Biliary obstruction is most often seen with growths about the papilla of Vater, and intestinal obstruction with neoplasms of the lower duodenum, jejunum and ileum. Gross bleeding or occult blood in the stools is a frequent observation in malignant tumors of the small intestine. Any patient presenting signs of intestinal obstruction, change of intestinal habit or melena, in whom studies have eliminated any pathologic change in the esophagus, stomach, colon or rectum, should be carefully studied to eliminate the presence of a malignant growth of the small intestine. X-ray study with a special barium sulfate series of the small intestine is generally recognized as the best positive means of diagnosis but, by itself, is not infallible. Of the twenty-two patients, eighteen are known to be dead. Of the survivors, three patients are living and well with no recurrence for periods of eleven years, three years and less than one year. A fourth patient was living with no recurrence for one year and has since been lost to follow-up. The surgeon and the roentgenologist should look for malignant growths of the small intestine so that the proportion of cases diagnosed early and cured may be increased.

Physical Defects and Scholastic Standing.—Woofter studied the relation of diseases and defects to scholastic standing of 360 unselected students near the same age from various primary schools. The grades were obtained for the previous semester and classed accordingly as excellent, good, fair and poor. A separate list was compiled demonstrating the defects of each child. In plotting grades of the same number of students it was found that excellent students were absent an average of two and one half days while poor students lost twelve and one tenth days. This observation is again borne out by contrasting the number of children with infected tonsils having excellent grades, which is 10.5 per cent, with those of poor standing, 31.5 per cent. Among 159 students having normal tonsils, 18.2 per cent could be classed as excellent and 16.3 per cent as poor. Therefore infected tonsils can be considered detrimental, if for no other reason than loss of time from school. One group of 230 students contained 152 with unclassified defects, minor or major, with an increase of 25.5 per cent among the poor students over those of excellent standing. Serious eye defects are apparently the greatest scholastic handicap a student can have, since only 4 per cent having a visual acuity of 20/40 or worse were excellent students, while 44 per cent had a poor scholastic standing. With normal vision 16.8 per cent were doing excellent work and 17.6 per cent poor. Of 231 unselected students, 24.5 per cent of the excellent students had eye defects as contrasted with 40 per cent of those doing unsatisfactory school work. Testing with the Betts eye view apparatus revealed a variation of from 50 to 75 per cent of failures to have defective vision. Malnutrition, that is, a weight of 6 pounds (2.7 Kg.) or more below the accepted normal for the height and age of that particular child, cannot be regarded as serious, except that underlying physical or environmental conditions should be corrected. The curve for these children is somewhat less satisfactory than the class average. The relation of deafness to class standing could not be definitely studied as only sixteen cases were discovered, but only a few of these are known to be doing unsatisfactory work. There was such a small group of children with speech defects that no conclusions could be reached.

Alternating Hemiparetic Migraine Syndrome.—Dynes records the cases of a mother and daughter who suffered from migraine and paralysis on the side opposite to that of the headache. They usually were warned of an approaching attack by prodromes: general malaise and chilliness. The attack itself was ushered in by numbness, tingling, marked weakness and loss of power in the arm and leg opposite to that of the headache. The migraine was not always on the same side, but the paralysis was always on the side opposite to it. Three years ago, at the age of 46, the mother was treated with radium for a uterine carcinoma. Her menses stopped. She has had no migraine headaches since and is in fairly good health at the present time. The daughter has noticed that a severe migrainous headache seems to be precipitated whenever her menstrual period is irregular and runs over the usual interval of twenty-eight days.

Ergotamine tartrate (0.0005 Gm.) given intramuscularly at the onset of one of her attacks altered the syndrome, as no hemianopia or paralysis of the extremities developed. The headache, nausea, vomiting and confusion which always accompanied the attacks were not relieved. The patient is being treated with estrogenic substance in an attempt to regulate her menses and also to evaluate, if possible, the effect on the migraine syndrome.

Acute Yellow Atrophy of Liver.—The two cases of acute liver atrophy that Townsend cites present certain features in common. Both occurred in puerperal women, in both a small amount of chloroform had been given and in each case the onset of symptoms had been preceded by vomiting with restricted food and fluid intake. In the first case the period of restricted intake was three days, but it was at a time when a great deal of energy was being expended and the extent of the diminished intake and its significance were not appreciated at first. In the second case diet had been restricted for three weeks because of preeclamptic toxemia, and fluid intake had been minimal for twenty-four hours following induction of labor, because of post-anesthetic vomiting. Each patient was partially exhausted and believed to have been partially dehydrated, though not to a degree recognizable clinically, and was given chloroform, a substance highly toxic to liver cells. The dangerous potentialities of chloroform in this respect have been shown by the work of Whipple and Sperry, Opie and others. It is suggested that these facts have an important bearing on the etiology of acute yellow atrophy: that exhaustion and dehydration are predisposing factors to hepatic damage, that a patient who is vomiting and dehydrated from whatever cause should be regarded as a potential candidate for hepatic atrophy, and that the administration of any protoplasmic poison or drug known to affect the cells of the liver be done with extreme caution, preferably preceded by saline dextrose intravenously. These cases also emphasize the importance of maintaining the strength and fluid intake of women during prolonged labor. Recovery of the second patient is attributed to the use of dextrose and abundant fluids and it is believed that the early and energetic use of dextrose and fluids is of prime importance in the treatment of acute yellow atrophy.

Sulfanilamide for Appendicular Peritonitis and Abscess.—Corry and his colleagues report the results obtained with sulfanilamide in the treatment of twenty-six cases of general peritonitis (with a mortality of 11.5 per cent) and fifteen cases of appendical abscess with no deaths. These forty-one cases came from a series of 232 cases of appendicitis and the three deaths gave a mortality rate of only 1.1 per cent. Of the patients who died, only one at necropsy still had a general peritonitis of the lower part of the abdomen and this patient had been given what is regarded as an adequate dose of sulfanilamide. When toxicity due to sulfanilamide occurs, the drug must be stopped. In several cases anaerobic and actinomycotic organisms were present in the peritoneal cavity. Since sulfanilamide has been of value against these organisms elsewhere in the body, it is reasonable to suppose that it was of value also in appendical peritonitis.

Hemochromatosis.—Harrington and Aitkenhead report two cases of hemochromatosis; one came under observation because of diabetes and the other because of hematemesis. Lawrence has recorded a pedigree which suggests that hemochromatosis may be a sex-linked hereditary disease, transmitted by women, and affecting men mostly. However, the authors state that in their cases there was no suggestion of familial incidence. The blood copper was normal. The only certain etiologic factor was alcohol, in which both had indulged freely. The woman patient had a large cirrhotic liver with moderate ascites, and a severe diabetes with little tendency to acidosis. The man, who also had a large firm liver and marked diabetes, had two fairly severe attacks of hematemesis but no ascites. Pigmentation was marked in both and appeared to vary in intensity from time to time. The prognosis is said to be uniformly bad but the introduction of insulin may prolong life. Of the present patients, the man is working as a commercial traveler. The woman, who was in poor social circumstances, kept very well, with no recurrence of ascites until she contracted septic complications which caused her death.

Trauma and Progressive Muscular Atrophy.—Turner says that the part played by trauma in the initiation of progressive generalized nervous diseases becomes occasionally subject to dispute in relation to workmen's compensation. In view of the lack of data derived from any notable series of cases, it seemed to him worth while to analyze a series of cases of progressive muscular atrophy to find out in what proportion a history of trauma exists. The term progressive muscular atrophy is taken to include amyotrophic lateral sclerosis and progressive bulbar palsy with muscular atrophy. The author studied a series of 100 consecutive cases. In thirty-seven cases there existed signs of progressive degeneration of the bulbar nuclei associated with generalized muscular atrophy and fibrillation either with or without evidence of involvement of the pyramidal tracts. Forty patients presented progressive muscular wasting associated with evidence of involvement of the pyramidal tract. Widespread muscular wasting and fibrillation of the classic type of progressive muscular atrophy without involvement of the pyramidal tract was observed in nineteen cases.

Postmortem confirmation of the diagnosis was obtained in four cases. For purposes of control a second series of 100 cases of other organic nervous diseases were analyzed. These 100 cases included patients of the same age groups and sex groups suffering from various organic diseases of the nervous system in which trauma is not thought to be an etiologic factor. A table records frequency of trauma in the two groups of 100 cases. There was no history of trauma in seventy-nine cases of the group with progressive muscular atrophy and in seventy-eight cases of the control group. Thus the total number of cases with a history of trauma was practically identical. It was only when an arbitrary period of a year was taken that a small difference in favor of the group with progressive muscular atrophy was apparent. In five of the cases of progressive muscular atrophy there was a history of injury within a year of the first symptom, and in three of these the injury was within a month of it. The author reports the details of these five cases. He reaches the conclusion that trauma has no primary part in the causation of the disease but in a small minority of cases seems to precipitate the appearance of symptoms.

Picrotoxin in Treatment of Barbiturate Poisoning.—Favorable reports on the use of picrotoxin as a physiologic antidote for barbiturate poisoning induced Lovibond and Steel to try this method in a case of poisoning of this type. The results which they obtained with the treatment were so striking that they feel justified in reporting the case. A woman aged 35 had been found unconscious in bed in the morning, having probably been in coma since the preceding night. The diagnosis of barbiturate poisoning was made from the clinical appearance of the patient and was afterward confirmed by the identification of this substance in the cerebrospinal fluid (cobalt nitrate and Millon's tests positive). On admission she was in a deep coma, collapsed and failing to respond to any form of stimulus. Until it was possible to obtain the picrotoxin some three hours later, the routine treatment for hypnotic poisoning was initiated. This consisted of gastric lavage, lumbar puncture, intravenous saline solution and intranasal oxygen. However, no significant change was observed in the patient's condition and she was still in deep flaccid coma when the treatment by picrotoxin was started. This was given by intravenous injection in divided doses of 2 cc. of a 0.3 per cent solution. The picrotoxin was at first given intermittently for two hours until the patient had been fully stimulated into effectual restlessness. For the next ten hours it was discontinued until a gradual relapse required a further 18 mg. In the intervening hours and subsequently, until 10 p. m. two days later, 4 cc. of coramine (a 25 per cent solution of pyridine betacarboxylic acid diethylamine) was injected intravenously at two hour intervals. A total of 54 mg. of picrotoxin and 112 cc. of coramine was given. The effect of the picrotoxin after every injection was dramatic and obvious, whereas no remarkable result was evidenced at any time from the coramine. The problem of dosage remains controversial but it seems that far larger therapeutic doses are both possible and safe. The authors gained the impression from this case that if it had been more severe they could with impunity have given larger doses of the drug. Intravenous picrotoxin should be given continuously until spontaneous movements, restlessness and a substantial decrease in the coma are apparent. After this, intramuscular injections may be sufficient to sustain the stimulatory effect. As a precautionary measure, barbiturates such as evipal or pentothal should be kept ready as a rapid antidote to an overdose of picrotoxin.

Familial Adenomatosis of Colon and Rectum.—During the last fourteen years, Lockhart-Mummery and Dukes observed the course of adenomatosis of the colon and rectum in ten families whose histories convincingly demonstrate the general familial character of the disease and its close relationship to cancer. The starting point in each case was a person with adenomatosis. As complete a family history as possible was

obtained from the patient, information being asked particularly about the present health or cause of death of parents, grandparents, uncles and aunts. Almost invariably the patient was aware of the high incidence of death from intestinal cancer among his relations. As many of the surviving relations were seen as was possible and sigmoidoscopic examinations were carried out. It was impossible to find out whether or not deceased relations dying of cancer had also been affected by adenomatosis. Probably in most cases the fatal cancer was secondary to adenomatosis. Although this disease is familial, it does not manifest itself as a rule before childhood or puberty. The age at which adenomas begin to develop varies in different families. In twenty cases the average age at which adenomas were discovered was 22. The tumors were probably present for at least a year or two before they were discovered; so the average age at which adenomas developed may be taken as about 20. In two families recently investigated by McKenney (1936) the average age was 19½ years. Malignant disease secondary to adenomatosis is characterized by its early onset and the fact that more than one primary focus of carcinoma may be present. Among the general population it is rare for cancer of the rectum or the colon to develop before 40 to 50, but in families affected by adenomatosis it often begins to develop between 30 and 40 or even earlier. The age of death from cancer in adenomatosis families is also younger (42 years) by about twenty years than in the general population. As a rule in families affected by adenomatosis the tumors begin to develop at about 20 years of age, malignant changes may be expected about fifteen years later and untreated patients die from cancer in the early forties. From an observation of the genealogical tables it is seen that the disease may be transmitted by either sex. In most cases only one parent was affected. In two instances there is evidence that both husband and wife died of cancer and in most of the descendants adenomas developed at an early age. In one family having twins, symptoms of adenomatosis developed in both twins at about 30 years of age. One was treated by colectomy at the age of 41 but died from the operation. His twin sister died of intestinal cancer also at 41. The familial character of adenomatosis is not congenital in the ordinary sense of the word, since it does not manifest itself for several years; but it is certainly due to an inherited defect, and the most likely explanation seems to be that it is caused by a gene mutation. Evidence is steadily accumulating that tumors are the result of a genetic change in a normal growing somatic cell. This explanation is applicable also to adenomatosis, in which disease the genetic defect appears to be a tendency to a more rapid growth of the intestinal mucosa, leading first to hyperplasia and later to adenomas. Because of the more rapid growth of the intestinal epithelium there must be a greater frequency of mitotic division, and this again increases the probability of a further gene mutation which manifests itself as cancer. In a rapidly growing adenoma the chance of this happening is much greater than in normal mucosa, in which mitosis takes place only at comparatively rare intervals. The explanation suggests that familial adenomatosis is the result of an inherited instability of the epithelial cells of the large intestine, which renders their nuclei peculiarly liable to undergo mutation for excessive rate of growth. The treatment of adenomatosis presents a difficult problem. Constant medical supervision is necessary so that a radical excision may be undertaken as soon as a malignant change is detected.

Bacteremia Following Tonsillectomy.—Elliott noticed a transient bacteremia in thirty-eight of 100 patients within a few minutes of tonsillectomy. Bacteria were found in the blood regardless of whether the tonsils were removed by blunt guillotine or by dissection. The organisms isolated included *Streptococcus pyogenes*, *Streptococcus viridans*, *Streptococcus pneumoniae*, *Haemophilus influenzae*, *staphylococcus* and *corynebacterium*. Serologic matches for *Streptococcus pyogenes* recovered from the blood were isolated from the corresponding tonsils after their removal. Hemolytic streptococci were recovered from the tonsils of eighty-seven of 137 patients undergoing tonsillectomy (64 per cent). Of forty-four cultures of streptococci so isolated and examined serologically, thirty-nine (86 per cent) belonged to group A, one to group B, one to group C (Lancefield) and three could not be typed. The source for the common occurrence of transient bacteremias in man and

animals and the possible bearing of these observations on the etiology of subacute infective endocarditis are indicated by the foregoing observations. Occasionally the causal organism in subacute infective endocarditis is of the hemophilus or parahemophilus group and that these organisms may be found in the blood after tonsillectomy is indicative. Of equal interest is the observation that pathogenic organisms such as *Streptococcus pyogenes* may circulate in the blood for short periods and in small numbers without producing any observable ill effect. The results of the tonsillar cultures here recorded suggest that some 60 per cent of patients admitted to the hospital for tonsillectomy carry *Streptococcus pyogenes* in the throat. Most of these patients had diseased tonsils, although it was not customary to admit cases for tonsillectomy within six weeks of an attack of tonsillitis. A carrier rate of about 60 per cent among patients admitted to the hospital for tonsillectomy emphasized the risk in otorhinologic wards of streptococcal cross infection, which a previous inquiry has indicated as happening not infrequently in the absence of special preventive measures (Okell and Elliott, 1936).

Pulmonary Condition of Stone Masons.—Moore and Kuhlmann determined the clinical and roentgen pulmonary condition of 355 employees in the stone mason allied industries in New South Wales, Victoria and South Australia. This has been accompanied by inspection of working conditions and the taking of dust counts. The existence of industrial pulmonary fibrosis of two distinct types was revealed, as well as evidence of other more acute respiratory disorders which may be the result of occupational conditions. Of 268 masons examined, 111 were found to be suffering from pulmonary fibrosis of moderate or advanced degree or from tuberculosis. This quota comprised seventy-nine cases of moderate fibrosis of the diffuse type (pneumoconiosis), thirteen of advanced fibrosis of similar type, eight of advanced fibrosis of silicotic type, two of pulmonary fibrosis complicated by active tuberculosis and one case of active tuberculosis only. The remaining cases were of doubtful tuberculous lesions, either alone or complicating a fibrosis. Cases of moderate fibrosis were not associated with incapacitation from work. Of the eight cases of silicosis detected, all except one were found among workers in sandstone, which has a high content of free silica (from 86 to 95 per cent). Workers handling this stone were found to develop fibrosis earlier and in a more severe form than those using granite or other stones with a low free silica content. The incidence of pulmonary fibrosis in marble and limestone workers was very low. Groups of workers examined, other than masons, including polishers and sawyers, were relatively small; but there is evidence to show that the disease develops among these workers. An apparently high incidence of emphysema and old or recent pleurisy was revealed by the roentgenograms.

Symptoms and Diagnosis of Uterine Cancer.—Despite the rarity of cancer of the uterus without bleeding, Mackenzie declares that it is imperative that curettement should be done in all cases of leukorrhea in which it is seen by the speculum that watery or purulent discharge is coming through the cervical canal. The size and consistency of the uterus have no vital bearing on the diagnosis of uterine cancer. In many cases there is no enlargement, but there may be enlargement, usually of a

uniform character, up to several times the normal size of the uterus. The mistake that the author has seen made has been in cases of enlargement of moderate degree in which a diagnosis of fibromyoma has been made, not corrected at operation, and supravaginal hysterectomy carried out at a level too near to the tumor for safety. He does not discuss the symptoms of advanced cases of uterine cancer. He believes that while the course which a disease runs should be sketched out for the student, the symptomatology of early disease only should be stressed and emphasized. Oversight in the diagnosis of cancer may be self excused on the ground that there were no pain, no ill smelling discharge and no deterioration of general health. The points of cardinal importance are that (1) irregular bleeding is the dominant symptom of carcinoma of the uterus, (2) such bleeding, at any age, must not be treated symptomatically and (3) the curet and the microscope must be used in diagnosis.

Modern Therapeutics: III. Calcium in Therapeutics. N. Morris.—p. 333.

So-Called Obstetric Shock.—An increased susceptibility to shock, Lochrane points out, is characteristic in labors associated with most of the toxemias of pregnancy. These conditions are held to be due to the circulation of incompletely disintegrated protein substances of fetal or maternal origin in the maternal blood. There is a toxic influence in the development of the shock-collapse picture in the majority of instances. The cause of the shock not infrequently reported to follow a supernormal degree of hemorrhage in obstetrics as in other more general conditions may not, at first sight, seem to be explained on the foregoing suggestions, as, in obstetric instances at least, hemorrhage is by no means invariably associated with gross trauma or pregnancy toxemia. The obstetric conditions with which the shock-collapse syndrome is most often associated (e. g. toxic accidental hemorrhage, placenta praevia, acute inversion of uterus, manual removal of placenta) emphasize the fact that trauma and toxemia in some, and trauma or toxemia in others, is incidental in greater or lesser degree to labor associated with such abnormalities. A distinction between the preliminary or primary shock phase and the secondary collapse phase of the shock-collapse syndrome appears to be justified in obstetrics. The percentage incidence of fatal degrees of shock in obstetrics is not large in comparison with the total incidence of the condition. In the absence of gross trauma, lesser degrees of primary shock of a more or less temporary nature may arise from some minor operative intervention such as the giving of a rather hot intra-uterine douche or the lifting of the fetal head over an intact perineum. The opinion may be hazarded that in these temporarily shocked cases there is a nerve center disturbance with little or no subsequent traumatic toxemia. In many of the more profound cases of obstetric shock the patient's condition may improve temporarily in an hour or so without major resuscitative measures, only to relapse into a worse state, the early nervous phase having been succeeded by the later toxic collapse. The observation that shock may be experienced after minor interventions without demonstrable gross trauma, undue hemorrhage or pregnancy toxemia in obstetric conditions provides the conclusion that, quite apart from any of these predisposing complications, there is an intrinsic variation in the degree of susceptibility of different individuals to shock. This seems to apply to both phases of the condition. At times there are obstetric patients in whom the degree of shock experienced is out of all proportion to apparent stress of labor. Here, if anywhere, there is a justification for the use of the term "obstetric shock" in a particular and restrictive sense.

In obstetrics there are other complicating conditions usually present which may well accentuate or even replace hemorrhagic and traumatic factors in producing a predisposition or an undue susceptibility to shock-collapse effects. Some of these are acidosis, a lowered carbon dioxide content of the blood, the extreme expenditure of muscular energy, waste products from muscular contractions and the blood-carbon dioxide reducing effect of most forms of inhalation anesthetics. It was shown by Yandell Henderson and later by Cannon that the fall in blood pressure which is a feature of shock is coincident with the lowering of the carbon dioxide content of the blood.

*Leptospiroses. B. Walch-Sorgdrager.—p. 143.

Leptospiroses.—In an extensive review on the subject of leptospiroses, Walch-Sorgdrager declares that the study of the disease was placed on a sound basis only when the specific cause was discovered by Inada and Ido, who transmitted the disease experimentally to guinea pigs in 1913 and discovered the spirochete which they called *Spirochaeta icterohaemorrhagiae* in 1914 and demonstrated that it is the actual cause of the disease. However, Weil's disease is not the only form of human leptospirosis. In Europe, but more especially in other continents—first in Japan and later in the Netherland East Indies, Federated Malay States, Russia, Andaman Islands, Netherlands and Australia—diseases have been described which are more or less related to it, though occasioned by other leptospirae. The several forms in man, and those occurring in dogs, rats and other rodents, are discussed in some detail. The author also discusses the epidemiology of icterohaemorrhagic leptospirosis in man and its clinical features, including incubation, clinical symptoms, complications, diagnosis, prognosis and treatment. Measures for the prevention of leptospirosis have been chiefly applied in countries in which the disease is prevalent, such as Japan, and also in countries in which it is not frequent but causes local epidemics, for example in slaughterhouses, baths and among seamen and sugar-cane cutters. Some of these procedures are the prevention of contamination of the ground and surface water with rat urine, the destruction of leptospirae in nature and the protection of workers in infected districts by preventing the organisms from penetrating through the skin or mouth. In places in which drainage and other measures are impossible or when the infected district is too large for disinfection to be effective, vaccination should be resorted to, for example in factories, mines, slaughterhouses, in instances in which the ratproofing of buildings is too costly or deratization is ineffective, on sugar plantations (on some Australian plantations the annual incidence of the disease among cane cutters sometimes reaches 18 per cent) and among sewer workers. When the risk of infection is limited to an occupational group, vaccination becomes practical. By immunization laboratory infections, where contact with rats is frequent and infections sometimes prove fatal, may be avoided. Wani mentions that he inoculated 10,268 miners in a coal mine in Fukuoka, 2,259 of whom received only one injection. The vaccination generally caused only slight discomfort: 50 per cent were able to continue working, 33 per cent lay off for one or two days and a slight rise of temperature or at least a complaint of a local feeling of warmth was experienced by from 30 to 40 per cent of the miners. Inoculation with other kinds of leptospirae than that causing Weil's disease, which are not in themselves dangerous to life (such as the leptospirae of "mud fever" or nanukayami) is of no value, as their immunizing properties, if any, are insignificant against Weil's infection. These kinds of leptospirae produce pathologic conditions, which are undesirable accompaniments of preventive inoculation. It is preferable, even essential, to vaccinate only with killed cultures. Health education and propaganda (films, lectures and the like) and compulsory notification are obvious necessities for an earlier recognition of cases as well as the stamping out of epidemic outbreaks.

Presse Médicale, Paris

47: 1277-1284 (Aug. 23) 1939

*Anorexia Nervosa and Its Immediate Therapy. P. Chatagnon and P. Scherrer.—p. 1277.

Anorexia Nervosa.—Chatagnon and Scherrer discuss the symptomatology and therapy of anorexia nervosa. Persons affected are generally women between the ages of 15 and 25 years. The clinical picture presents the following features: gradual self restriction of food leading to extreme emaciation, with a possible decline from a weight of 132 pounds (60 Kg.) to 55 pounds (25 Kg.); excessive physical and mental activity in striking contrast with the physical deterioration; the growth of bizarre, onesided gastronomic tastes, e. g. for prunes, biscuits, olives, unseasoned salads and so on; complete apathy in the face of bodily degeneration. Food forcibly administered is rejected by self-induced exertions. Amenorrhea is present. Usually there is found a neuropathic heredity and an unfavorable family environment provoking, on occasion, an inferiority complex toward a successful member of the family of the same sex. In certain cases the psychosis may be prodromal to dementia praecox; the majority of the patients develop conditions bordering on obsession. The occurrence of death is exceptional; however, some investigators set the mortality rate at 13 per hundred. Relapse after recovery is always possible. The authors discuss and reject the various views of others of the nosologic classification of anorexia nervosa within the framework of an established neurosis; neither do they favor an endocrine etiology of the disease, in spite of parallel indications simulating anorexia nervosa. They differentiate particularly between anorexia nervosa and Simmonds' syndrome. In Simmonds' syndrome emaciation develops gradually without an appreciable food diminution or, in its incipience, with none at all; there is present only a simple loss of appetite or distaste for certain foods, which the patient may seek to overcome and for which the metabolic dysfunction of his organism penalizes him by diarrhea; mental disorders are late, characterized by melancholia and unaccompanied with physical self neglect. On the other hand, in anorexia nervosa emaciation is the direct result of a food refusal that excludes all cooperation of the patient to improve his condition, the patient not only forcibly resisting alimentation but deliberately regurgitating what he has consumed; mental disturbances are immediate and compatible with a high degree of alert activity. Even amenorrhea is of a secondary nature in anorexia nervosa. According to the authors, therapy consists in isolating the patient in a sanatorium or hospital, in artificial alimentation and in psychotherapy, to the exclusion of medicaments of all kinds. Therapy will vary according to whether the patient is in an advanced or an incipient stage of the disease. Artificial alimentation in both classes of patients consists, with due regard to the age of the patient, of two daily doses, preferably of raw sweet milk with the addition of the yolks of one or two fresh raw eggs, together with fresh fruit juices (lemon, orange and so on). To restore tissue balance, from 250 to 500 cc. of dextrose solution is daily administered subcutaneously for a variable period and occasionally physiologic solution of sodium chloride. Reeducation of the patient in the use of his muscles needs also to be done. In cases presented at once for clinical study, psychotherapy should be employed immediately and should enlist also the cooperation of the family physician. Readjustment of the patient to social and family environment after her release from the institution constitutes a problem.

Arteriosclerosis and Adrenal Capsule Lipoid Epinephrine Complex.—A close connection between the formation of arteriosclerosis and the functioning of the adrenal capsules has been frequently assumed, based on the following observations:

arteriosclerotic changes in the vessels of youthful individuals with adenomas of the medulla or tumors of the cortex of the adrenal capsules and in Cushing's disease usually accompanied with hyperplasia of the cortex; degenerative changes in the arterial muscular layers of animals corresponding to media-sclerosis, produced by protracted injections of epinephrine; increased infiltration of cholesterol in the intima of the aorta of rabbits following administration of epinephrine; a tissue cholesterol fixing faculty of the cortex hormone; changes produced in the vessels by repeated implantations of the entire substance of the adrenal capsules, which however do not quite correspond to typical arteriosclerosis. Recent research drew the attention to the close morphologic, functional and even physical and chemical connections between the products of secretion of the medulla and the cortex of the adrenal gland. Investigations on the constrictive effect of lipoid epinephrine compounds directed Raab's attention to the problem of a lipoid-epinephrine complex presumably formed in the adrenal capsules and the characteristic way in which it affected the structure of the wall of the artery. He carried out experiments on groups of animals with lipoid epinephrine complexes obtained from the adrenal capsules of animals and from the serum of persons with arteriosclerosis and hypertonia, assuming that the lipoid epinephrine complex should likewise be present in the serum. The extracts did not contain free epinephrine or cholesterol and produced the following effects in experimental animals: increase of blood pressure; increase of blood sugar; general nervous irritation such as trembling, nervousness, eventually edema of the lungs and death; injury of the media of the aorta, such as necrosis and calcification; injury of the intima, such as loosening and thickening, and an increased deposit in the intima of cholesterol ingested with food. As to the modifying effect of lipoids on the epinephrine in the lipoid-epinephrine complex, a satisfactory chemical explanation is not available at present. On the basis of these results as well as numerous clinical, pathologic and anatomic data the following factors appear to be of importance in the etiology of arteriosclerosis: prolonged action of an adrenal capsule lipid epinephrine complex on the vessel wall; protracted ingestion of food with large amounts of lipoids and cholesterol in particular, whose deposit is increased by the adrenal capsule lipid epinephrine complex; disposition of the vessels to the attacks of these injurious agents. According to the author, the frequent simultaneous occurrence of arteriosclerosis, high blood pressure and diabetes can perhaps be explained by the action of the adrenal capsule lipid epinephrine complex.

*Measurement of Venous Pressure in Thoracoplasty Patients. K. S. Stein.—p. 323.

Venous Pressure After Thoracoplasty.—Stein tabulates the results of his bilateral determinations of the venous pressure of forty-six patients, thirty-six before and after the first session of thoracoplasty, twenty-two of these also before and after the second session, seven patients before and after repeated plastic operation several years after the first operation, one patient with thoracoplasty according to Monaldi, one patient with plombierung and one operated on for pulmonary abscess, with drainage; the conditions which might be assumed to play a part in the venous pressure are also noted. In the majority of the cases operation was followed by a rise in the venous pressure, usually brief, the venous pressure in thirty-one cases becoming normal on from the seventh to the seventeenth day. There was no definitely established relation between the height of the venous pressure and the operative course. Preoperatively increased venous pressure, the author says, is not always an indication that operation will not be well borne. Theoretically he ascribes the postoperative increased venous pressure to changes in intrathoracic pressure and stasis in the vena cava superior region, but he thinks there may also be other causes; in some cases heart disease may be at least partly responsible, since electrocardiographic changes were often observed, and the fact that in most of the cases there was a considerable fall in the blood pressure during the operation might point to changes in the peripheral circulation as a factor.

Organization of the Small Hospital Library

WILLIAM D. INLOW, M.D.

SHELBYVILLE, IND.

From time to time the American Medical Association¹ through the Council on Medical Education and Hospitals issues suggested lists of medical books and journals suitable for hospital libraries. Such libraries are now required in all institutions approved for the training of interns and for graduate study in the specialties. The library requirements of the private clinic and of various medical associations are similar to those of the hospital and can be considered with them. The Council in its recommendations discusses the organization of such a library only in the briefest way, leaving aside entirely the problem of the classification of the collection which would accrue if their suggestions should be followed.

The needs, aims and uses of the library in the hospital and clinic are special and differ both from those of the public library with a medical department and from those of the large medical library associated with a medical school or research institution. Its function is practical and clinical. In the hospital it exists for the use of the intern and the attending physician; in the clinic it is consulted by the staff for aid in the solving of the many problems that daily arise. Stress therefore comes on the fields of diagnosis and of therapeutics, and the requirements in the departments of fundamental medical science and medical research are not great.

The type of library here described has its chief role to perform in the small city more or less isolated from the large medical center. It is frequently impossible for the individual practitioner to purchase a sufficient number of books or to subscribe to enough journals to give him anything more than the most meager reference store. Too often he has but few books, and his journals are unbound, stored away and unavailable. Libraries in small hospitals gen-

erally are made up of gifts or brought together by the pooling of individual collections and are supplemented by unsystematic and intermittent new purchases and subscriptions. There is no paid librarian, the use of the material is not great, no organization exists and interest lags. It is doubtful whether many such collections justify their existence.

All worth-while journals should be bound. Periodical files are the most valuable part of any medical library. Here only is the living advancing front of medicine visible. Here only in many instances can be found that detail of information concerning specific subjects necessary for the most successful prosecution of medical practice. Periodicals, however, offer little difficulty in classification, for they may be placed simply on the shelves in alphabetical order, and all material which they contain is readily available through the *Quarterly Cumulative Index Medicus* and other indexes.

The chief task therefore in library organization has to do with classification of the store of books. These may be recent or old. The shelves tend to accumulate many volumes that appear out of date. Some of these, generally gifts of collections assembled a generation or two ago, are so old that their material is of historical interest only. Others, more recent but still not new, contain a surprising amount of valuable content applicable to modern practice. There is a tendency among medical men to consider solely works of very recent publication worth their attention. In a certain few fields, where changes are rapidly taking place, they are doubtless right, but with regard to the bulk of the fundamental information on which medicine rests they are not. Especially when such books are supplemented by the record of contemporary progress depicted in the periodical literature, they are still worthy of a place on the active working shelves. However, in a library used chiefly by interns, who may rely largely on textbooks, it should be seen to that these are recent.

From the Inlow Clinic.

Numerous suggestions and criticisms were made by Miss Bertha Bowlby, librarian, Carnegie Public Library.

1. Hospital Medical Library Suggestions, J.A.M.A. 108:1052-1059 (March 27) 1937; 102:1785-1791 (May 26) 1934; 92:1122-1127 (March 30) 1929; 84:980-983 (March 28) 1925. Jenkins, R. L.: Periodicals for Medical Libraries, *ibid.* 97:608-610 (Aug. 29) 1931.

Among the older books, a few will be found worthy of the title of medical classic, works deserving perusal on the basis of their own intrinsic value and persistent significance in the history of medicine. These should be culled out and placed in a separate division. Other older books will have value only as being representative of the medical knowledge of the particular time in the specific field represented, and of course there is little point to collecting these unrestrictedly. A few illustrative works for each field in each period will be found sufficient. Most of these older books will come within the nineteenth century, for they will have been derived largely from American sources. Books older than this again deserve separate space and, if rare and valuable, may be put under glass.

Information concerning the details of library cataloging, and the getting ready of books for lending is easily available; it is given in sufficient fulness for the small library in the pamphlet issued by the Library Bureau.² It is chiefly with the classification of the books themselves that I am here concerned.

CLASSIFICATION OF BOOKS

Many methods of classification for medical libraries are in use and have been suggested; any one chosen will be found to be more or less arbitrary.³ In 1920 the Medical Library Association adopted the Boston Medical Library Classification⁴ as a standard for American medical librarians. It has much to recommend it, and it may seem superfluous as well as presumptuous to offer anything different. It has withstood the test of time and is in active use in many libraries. As is true of any good classification for general medical needs, it attempts to "refrain from any bias of an anatomical, physiological, clinical or surgical nature." The type of library which I am discussing possesses a bias, namely the clinical one. No more apology is needed in following it than in excusing the medical bias exhibited in all medical libraries with regard to knowledge in general. Libraries are of different sorts and exist for specific purposes. In formulating a classification primarily subservient to clinical requirements, however, it is still possible to have a system elastic enough to be adaptable to other ends.

The Boston schema has forty-two main classes denoted by numerals. Further division is car-

ried out by the use of the alphabet, the second place in the notation being occupied by capitals and the third by small letters. This gives the possibility of twenty-six primary and twenty-six secondary subdivisions.

Phalen and Garrison present two main headings, "Basic Disciplines" and "Medicine and Subdivisions," under each of which in separate lists are given one group of disciplines as "Subject" and another group as "Congeners or Related Subjects." There is no further attempt at integration and no notation other than single arabic numerals given to the main topics under "Subject." Barnard, using the alphabetical method of notation, divides the whole field of medicine into twenty-six classes, with numerous divisions, subdivisions and sections. His classification obviously has been developed for the use of the very large institution, one rich in the field of tropical medicine and parasitology, and its basis is largely etiologic. None of these schemata seem to meet the needs of the small clinical library.

What are these needs?

Any system adopted must be simple and at the same time susceptible of indefinite expansion. It must be one that can be administered on occasion by the record clerk or clinic secretary, untutored in the intricacies of library management; it must be one by which the average physician rapidly and readily can find the material he wants without assistance; it must be compact yet comprehensive in that it must include all fields in which the physician is likely to seek help.

The classification of the Boston Medical Library was formulated with the idea of bringing "together under one heading all material of a special nature," so that everything "relating to a system of organs or individual organs, whether of an anatomical, physiological, pathological, clinical or surgical aspect, is put in one place." This is quite admirable so far as the systematic theoretical study of medical topics is concerned and doubtless fits well the requirements of many institutions. However, in a library made use of as an adjunct to active medical practice, such concentration hinders rather than expedites the clinician's work.

Furthermore, forty-two or even twenty-six classes are too many for rapid orientation. Letters are less easy to follow and to associate with certain topics than are numerals. Since 1879 the Dewey⁵ decimal system has been in use in great numbers of public libraries. It has been elaborated on and added to in each subsequent edition until it leaves little to be desired for the needs of those general lay institutions

for which it was designed. In it the whole field of knowledge is divided into ten classes (general works, philosophy, religion, sociology, philology, natural science, useful arts, fine arts, literature, history), which are subdivided and resubdivided decimally ad libitum. Medicine is given

section in this classification, however, shows the organization of the medical field itself far from satisfactory from the clinical standpoint. The domains of anatomy, physiology and public hygiene are adequately and exhaustively treated, but many other fields are sadly neg-

System of Classification for the Small Library in Hospital and Clinic

Class 0 00 Generalia, Reference Works 01 Bibliography 02 Nomenclature, terminology and classification 03 Dictionaries 04 Languages, grammar, composition of scientific papers 05 Encyclopedias — general 06 Encyclopedias — medical 07 Collections of tables, formulas, useful data 08 Directories 09 Atlases 10 Commercial publications, price lists, trade catalogues	Class 5 50 Diagnosis, Technical Methods 51 General works, medical and surgical diagnosis 52 Symptomatology, semeiology 53 Clinical methods, history taking 54 Physical and instrumental diagnosis 55 Laboratory diagnosis, chemical, bacteriologic and microscopic 56 Electrodiagnosis, electrocardiography 57 Roentgenologic diagnosis 58 Postmortem examination, microtechnic 59 Differential diagnosis 60 Prognosis
Class 1 10 General Science 11 General works, scientific method 12 Mathematics 13 Physics 14 Chemistry 15 Geology, geography, meteorology 16 Biology 17 Anthropology, anthropometry, constitution, ethnology 18 Psychology 19 Sociology 20 Philosophy	Class 6 60 Therapeutics 61 General works 62 Personal hygiene 63 Dietetics, nutrition, vitamins 64 Pharmacology, materia medica, toxicology 65 Vaccine and serotherapy 66 Hydrotherapy, climatotherapy 67 Mechanotherapy, massage, exercises, gymnastics 68 Physical therapy, electrotherapy, actinotherapy 69 Radium and roentgen therapy 70 Psychotherapy, psychoanalysis
Class 2 20 Medical Science 21 General anatomy 22 Topographic anatomy 23 Embryology 24 Histology 25 Physiology 26 Physiologic chemistry, biochemistry 27 Pathology 28 Bacteriology, parasitology 29 Serology, immunology, allergy 30 Experimental medicine, research	Class 7 70 Social Medicine 71 Social medicine, marriage, sexology 72 Public health, preventive medicine, racial hygiene, eugenics 73 Epidemiology, geographic medicine 74 Biometry and statistics 75 Industrial medicine 76 Medical jurisprudence 77 Medical education, medical schools, museums 78 Medical societies 79 Medical economics, state medicine, health insurance 80 Medical profession, medical ethics

Class 4 40 Surgery and the Surgical Specialties 41 Manuals, textbooks, systems of general surgery 42 Anesthesia, operative surgery 43 Minor and traumatic surgery, first aid, bandaging 44 Fractures and dislocations, orthopedic surgery 45 Ophthalmology, otolaryngology 46 Oral and plastic surgery, surgery of head and neck 47 Neurosurgery, thoracic surgery 48 Abdominal surgery 49 Urology, proctology 50 Gynecology, obstetrics	Class 9 90 Associated Medical Fields, Miscellaneous 91 Mysticism, faith healing, cults 92 Tropical medicine and hygiene 93 Military and naval medicine, aviation 94 Comparative and veterinary medicine 95 Dentistry 96 Pharmacy, pharmaceutical manufacturing 97 Nursing 98 Hospitals, clinics, research institutions 99 General literary works 100 Medical miscellany, collected papers, transactions, reprints, government reports, etc.

the number 610 and listed under useful arts along with engineering, agriculture and domestic economy.

The decimal system used in this classification recommends itself immediately for adoption in spite of certain criticisms of its use. For instance, a misplaced point or a forgotten numeral works havoc. Errors of notation are possible in all systems, and this seems small justification for rejection. Study of the medical

lected, in fact just those most important in a working clinical library.

Any system of classification may have many valid criticisms leveled against it, and no general formula can be found which fits all needs. In presenting therefore a classification of my own, based on the Dewey system, with certain borrowings from many other sources, I appreciate fully that it represents solely the schema which has been found by experience to fit the

needs of one organization, the library of the Inlow Clinic. It is in the belief, however, that libraries very similar in their requirements to this one exist that the suggestions herein made are offered. This classification in outline form should be posted in a prominent place in the library. Furthermore, the ten main headings and many of the chief subheadings should be clearly indicated on the shelves by large labels. The shelves should be arranged so that the numbers follow in regular succession and little difficulty is experienced by any one coming into the library for the first time in locating the field he is seeking. Much material is thus readily available without consultation of the card index.

CATALOGUING OF BOOKS

Cataloguing in many instances may be difficult. Many works fall under more than one heading. It is best to place the book under that caption in which it appears to have most use in the individual institution. The whole spirit which should activate the clinical library is that of utility. Other headings under which a book may come are adequately taken care of by listings and cross references in the card catalogue.

It will be noted that this classification attempts an organic integration of medical knowledge and associated fields. It is functional and instrumental. In the formation of the classes and divisions I have followed in a broad way the order in which subjects are met in the course of medical education. From the standpoint of the intern this is desirable, for it is the sequence to which he is accustomed. First come the tools with which the physician works: indexes and volumes for ready reference, volumes on the languages, dictionaries and encyclopedias. The languages are the means by which medical writings in other tongues are made available. Preliminary bibliographic investigation is the *sine qua non* for the adequate tapping of periodical literature, and cyclopedias furnish rapid orientation in any subject. Then there is the broad field of scientific and medical knowledge in general. This is the material collected through the centuries, and it naturally falls into three groups: (1) the whole gamut of the natural and the social sciences with the exception of astronomy; (2) the medical sciences, those sciences which, though forming a part of other disciplines, nevertheless may be taken as integral parts of medicine itself, and (3) those subjects detailing the natural history and course of disease which constitute the true content of clinical knowledge.

Mathematics is the handmaiden of all the sciences; physics, chemistry and biology are at the basis of physiology and of pathology; geography, geology and meteorology have their role in geographic medicine and climatology; anthropology and psychology furnish material for the understanding of man himself; sociology is the

basis for many problems in preventive medicine, public health, medical jurisprudence and medical economics, and true critical philosophy is the discipline which weaves all these things together into an organic whole for the development of an adequate scientific world view.

The listing of the medical sciences here employed is quite familiar, since it includes those subjects encountered in the first two years of the usual medical course. The field of experimental medicine and research naturally fits in with this group of distinctly scientific studies.

In the practice of curative medicine, so called, the end which hospital and clinic subserve, there are two elements: the store of knowledge with which the practitioner works and the technical means at his disposal for the recognition and the control of disease. These two fields greatly overlap, and many works, especially those on medicine, surgery and the various medical and surgical specialties, contain material concerning both. Though in theory the knowledge on which curative medicine is based forms one integrated whole, yet from the practical standpoint it is divided into medical and surgical portions. Surgery in the strictly philosophic sense is merely a branch of therapeutics, the operative treatment of disease. In practice, however, it has assumed such importance and taken unto itself so much of the content of medical knowledge and theory that it approaches or equals the domain of internal medicine itself, especially so far as hospitals and private clinics are concerned, and should therefore be given separate consideration in any clinical library classificatory scheme.

The field of medical knowledge and practice has been divided into specialties. According to whether the medical or surgical element in these (for each specialty contains something of both) predominates, they may be classified either as medical or as surgical specialties. This portion of the clinical library, which I have placed under classes 3 and 4, doubtless will outweigh any other, for it will contain many of the books forming the real working nucleus of the entire collection.

The real function of the practitioner on the hospital or clinic staff is the recognition and the treatment of disease processes. His literary working tools lie largely in the fields of diagnosis and of therapeutics. Prognosis may be taken as a part of diagnosis; there are few works devoted to this subject alone. Some specialties will be found to owe their existence to diagnostic and therapeutic needs. Such, for instance, are clinical pathology, roentgenology and physical therapy. The domains of diagnosis and of therapeutics are fairly well separated, but in making of them separate classes roentgenology, which consists of diagnostic and of therapeutic elements, is separated on the

shelves rather than located in a single place, which would be more desirable to a specialist who united the two fields in his practice. No matter what system of classification is adopted, it will be found that such separations will somewhere have to be made.

The clinician as a rule in consulting the library has some specific problem in mind. He may already have made a tentative diagnosis, for example of trichinosis. His knowledge of this subject, however, may be hazy, for it has been a decade since he has observed a similar case. He consults the library for systematic information on the subject. He will turn to the section on general medicine therefore, where he will find in sufficient detail the material to satisfy his immediate needs. The laboratorian to whom he sends a specimen of stool or blood for verification of his diagnosis will consult the division of laboratory diagnosis. Only if they are curious to know more of the life history of *Trichina spiralis* will the clinician and laboratorian consult the division of parasitology in the class medical science. There are degrees of need and interest exhibited by those who consult the library and gradations of the extent to which any subject may require investigation.

THE CLINICAL LIBRARY

The problem, on the other hand, may be a purely diagnostic one. The clinician may wish not to overlook any of the possibilities relative to a presenting symptom; he may desire to verify what he can expect from some particular test; he may already be reasonably certain that the case is a medical or a surgical one but still be not satisfied as to just what is going on. He will consult the diagnostic divisions. Or again he may have arrived at a diagnosis and be undecided as to what is the best procedure to follow in treatment. Just what may be expected in this instance from physical therapeutic procedures? He may know the drug or endocrine preparation he wishes to give; but in what form and in what dose shall he prescribe it? This patient desires to go to a certain resort for rest and recuperation and asks for information concerning it. This one needs a certain diet. To answer these questions and to meet these desires he will consult the therapeutic section.

This brief discussion shows how in a clinical library attempted concentration of all material concerning one topic in one place may hinder instead of expedite diagnostic and therapeutic work. A library of this kind is of more service when it is departmental, that is, when the classificatory division is made on the basis of the separation of the field of medical practice among various types of practitioner (internist, surgeon, ophthalmologist, urologist, roentgenologist, laboratorian, physical therapist, dentist, nurse) rather than on the basis of anatomic

part or etiology. It leads to less confusion to have each specialist find the whole field in which he is primarily interested segregated in one part of the library without finding also before him on the shelves works concerning the topic in question treated from points of view which have little bearing on his particular approach.

In the classification here proposed, material on various topics is scattered purposely. If the practice of medicine in hospital and clinic were not itself departmentalized (specialized) this would be a serious drawback, but with conditions as they are this is not the case. It is seldom indeed that any one working in a clinical institution will consult the library to find out all that it contains about any one particular topic viewed from every possible approach. The place for concentration of all material concerning one subject is in the card catalogue and not on the shelves. For in fact the ideal of concentration aimed at in some classifications cannot be attained; some dispersion is inevitable from the very fact that most books discuss many topics but permit themselves physically to be put only in one place.

Medicine has broad social as well as individual personal functions to perform. There are those fields which have to do with the control of disease *en masse*, the topics of public health and preventive medicine; those which have to do with the application of medical knowledge to the solving of strictly social problems, such as the subjects of medical jurisprudence, criminology, juvenile delinquency. There is the domain of the relation of physician to patient, physician to physician and physician to society, medical ethics; that of the application of knowledge in a department of sociology, economics, to the problems of medical organization and practice. There is the charge of transmission of medical knowledge from one generation to another, medical education. All these I have segregated under the class social medicine.

Medical history is a part of cultural medicine. This subject has assumed such large importance in the field of medical bibliography that it deserves to be placed as a separate class. As a division under this are grouped all obsolete works of the nineteenth century. Besides being assigned their own distinctive notation, these volumes are classified according to the general schema, i. e. they likewise are assigned the number of the subject of which they treat. By this means two things are accomplished: 1. The seeker after recent information in any field does not find the shelf of his subject cluttered up by nonusable books. 2. He who is historically minded can find what he desires already separated for him. By this procedure gifts of old books can be put to their proper use.

The divisions of the last class, that of miscellany, are in a way parts of social medicine. Clubs, hospitals, sanatoriums and pharmacies, as well as veterinary medicine, dentistry and nursing are social institutions. Yet on practical grounds they belong in a group by themselves.

Naturally in the artificial placing of the whole field of medicine in classes and divisions of ten there will be apparent crowding of subjects in one place and lack of sufficient diverse headings in another. From the standpoint of making material available this drawback is more apparent than real. Throughout, those subjects have been grouped together which are allied either organically on the basis of content or in accordance with medical custom. Thus ophthalmology and otolaryngology are placed together, neurology and psychiatry and so on. These fields are similarly united in the person of a single practitioner in many of the smaller medical centers. However, though two or more specialties in many instances are placed under the same division, they can be separated easily as the library grows by the addition of a distinctive further notation.

SUBDIVISION OF SUBJECTS

In order to present the classification in as simple a manner as possible I have offered here only 100 headings over the whole medical domain. Even small libraries, however, will find it desirable in certain fields to go beyond this. Besides classes and divisions, subdivisions and sections can be established by adding a decimal point and more numerals. The use of more than four digits will seldom be found necessary even in the largest libraries. It must be emphasized that subdivision carried too far becomes a hindrance instead of a help.

The method of further classification can be explained briefly. In the instance of two or more main subjects grouped together under the same two digit symbol, these topics can be separated by the addition of letters from the alphabet to designate them, as employed in the classification of the Boston Medical Library. Thus, for example division 44, class 4, becomes broken up into 44A ophthalmology, 44B otology, 44C rhinology, 44D laryngology, and so on.

Small hospitals today are largely surgical institutions. Surgery rests on the disciplines of anatomy and pathology. The human body is readily divisible into various structures and organs; pathologic processes are easily recognized as being of different kinds. Further classification in the surgical specialties therefore naturally makes use of these time honored divisions; the anatomic classification will vary with the specialty and the organs and body system involved; the pathologic classification is largely the same for all structures. The subdivision is created on an anatomic basis and the section on a pathologic one. Thus,

division 47, abdominal surgery, falls into subdivisions 47.0 general works, .1 abdominal wall, hernia, .2 peritoneum, .3 stomach, .4 intestine, .5 liver, .6 gallbladder and bile passages, .7 pancreas, .8 spleen, .9 mesentery, miscellaneous. The same method of subdivision is applied to thoracic surgery, urology, gynecology and other branches. The pathologic classification is .00 surgical and pathologic anatomy, .01 anomalies and malformations, .02 regressive and degenerative changes, .03 disturbances of circulation, .04 general inflammations, .05 specific inflammations, tuberculosis, syphilis, etc., .06 changes in lumen, position, size, .07 injuries, .08 foreign bodies, concretions and parasites and .09 tumors. Thus, for instance, a surgical work on carcinoma of the stomach would be labeled 47.39.

In other classes the basis of division cannot of course be anatomic and pathologic but must be suited to the material in hand. For instance, the division periods in medical history can be subdivided into .0 prehistoric medicine, paleopathology, .1 ancient medicine, .2 Graeco-Roman medicine, .3 Byzantine period, .4 Mohammedan and Jewish period, .5 medieval periods; .6 renaissance and reformation period, .7 seventeenth century, .8 eighteenth century and .9 modern period.

By subdivision and further elaboration, unlimited expansion can be taken care of, and, though designed for the use of the small library, the classification can be employed for the largest clinical collections.

It must be emphasized, however, that the particular system of classification adopted is not as important as the fact that any library larger than a certain minimum size has to be organized if any one other than the person who has seen to amassing it is to make maximum and effortless use of it. Systematization and order are requisites to all intellectual housekeeping.

18 West Washington Street.

Red Blooded Young People

A prime fascination of medicine is that it is a never ending study. Merely not to forget what you have learned cannot keep you ready for the obligations of medicine. Without forgetting anything that you learn in medical school, soon as physicians, surgeons, specialists, etc., you will become hopelessly behind the times, unless you continue to study. Not forgetting will not keep you from rapidly losing out in medicine; what you may know soon is apt to be completely outmoded by new discovery. In your medical school days, I dare say, this idea of a never ending study did not seem such a joy. However, how dull a profession medicine would be if in a four years study in the medical school you had learned all that was needed to practice the profession the remainder of your lifetime. That sort of a profession would not attract into it red blooded young people.—Christian.

Comments and Reviews

THE PRACTICE OF MEDICINE

Abridgment of an address by Dr. Rufus Cole, delivered at the commencement exercises of Cornell University Medical College, June 15, 1938, and published in Science, Oct. 7, 1938.

The subject of medicine is sufficiently important and the knowledge concerning it sufficiently well organized to justify its designation as a science, and its devotees are worthy to be called scientists. Under these circumstances it seems that medicine would be a proper subject to be taken into the university as a discipline worthy to be studied, even if all applications were entirely lacking.

The question remains whether there are reasons why future practitioners should pursue the subject from this point of view. It is possible that a student might, through repeated observation and didactic instruction, become familiar with the characteristic features of disease, that he might learn empirically the procedures employed in treatment and that he might through experience alone acquire skill in prognosis. Formerly this was about all that was attempted in the training of physicians. But the university and society at large now demand that physicians shall be familiar with what is known about the nature of the processes constituting disease and of the lesions associated with them. The phenomena of disease are natural processes occurring in conformity with the laws of nature, and these phenomena can be understood only by using methods universally employed in revealing the mechanisms of other natural events. These are the methods of science. Now are you trained physicians ready for practice?

You may have knowledge of the structure and functions of the human organism in health. You may be able to picture at a moment's notice the characteristic lesions of all diseases, to pass a perfect examination on the functional disturbances produced by all types of injurious agents, and yet you may not be a good physician. There is such a thing as the technic of practice and this technic you cannot learn in the true university medical school. No one except the self-deluded men who examine you for license to practice expects you on graduation to be proficient practitioners. This does not mean, however, that you are not well prepared to master the technics necessary to make you good physicians.

It is not easy to differentiate between the study of the science of disease and the practice of medicine. The practitioner is primarily interested in the diseased individual and he must concentrate attention on those features the importance of which has been demonstrated. The university student may spend days in the

investigation of a single case. The practitioner must investigate, judge and act quickly. The university lays stress on complete understanding; practice lays stress on skill. It is not a question of treatment. The patient no longer employs a physician merely to have him administer remedies. But what he rightly demands, first of all, on the part of the physician is understanding of his entire constitution as an individual. The university student and the practitioner both are interested in treatment, but the practitioner is especially concerned with the technics employed in the individual case. Whatever the differences, the university student and the practitioner must both employ the methods of science. They must both have the scientific habit of mind, and this is especially what the university should give. Both must have curiosity, the desire to learn; both must have honesty, and both must be critical. Unverified opinion can have no place as guides to action.

If you have not yet acquired the technic and skill for practice, how are you to get it? It can be acquired only by practice itself and by hard unremitting labor. In earlier years the rudiments of the technic of practice were obtained by following a preceptor and, so far as it went, this was not a bad way.

THE WEAKEST LINK

Today the preceptor system has been replaced by the hospital internship and there are defects in the intern system. It is the weakest link in present day medical education. In most cases all the hospital does is to offer opportunities to the intern. The preceptor cared whether the student did or did not learn, the hospital usually does not care. But hospital physicians can be interested in the training of interns, to their own as well as to the student's great advantage. Hospital authorities can undertake more seriously their educational responsibilities.

In the first place the hospital can realize that its interns are highly educated, cultivated, serious men whose ambition is to serve the patients under their care and whose greatest desire is, through practice, to become technically skilful, more gentle, more humane, more wise. The hospital can provide facilities so that interns may live like cultivated men and students; this does not mean provision for higher standards of living but for higher standards of work and study. When visiting hospitals I have made a point of seeing the interns' rooms. Even in some of the most modern hospitals I usually find small, dark rooms, containing a bed, a chair or two, a small desk and a few books, and these mostly textbooks, remnants of the student life. I was surprised to find no evidence of any interests at all, even in science. To find that a

young man could have acquired a university degree and have no interests outside his daily job was a surprise. The hospital cannot create these interests but it can assume that the intern has them. The hospital should not treat interns as employees and provide to the minutest detail the kind and amount of work they shall perform. Interns must have freedom. This in large hospitals is difficult but not impossible.

I recall experiences under Osler. He was personally interested in every intern, considerate of their sensibilities and their time; he seized on the least evidence of curiosity in an intern, stimulated his interest and aided him with advice and help. His contacts with his interns were not confined within the wards. He never missed a meeting of the hospital medical societies. Above all he influenced the interns by his example. He taught them to become good doctors by being one himself. All practitioners connected with large hospitals come daily into contact with the interns. By spending a limited amount of time with them, by guiding them, by working with them, these practitioners may be of great educational service. Practitioners in a small place have the same opportunity to become great teachers as had Daniel Drake in the little Transylvania University beyond the mountains.

After all, whether interns become good doctors or not depends on the interns themselves. Our hospitals have arrangements for making all kinds of technical investigations. The intern becomes a part of this organization and he is able to use any one of a dozen different laboratories to aid him. This is useful but it carries with it dangers. The student begins to deal with formulas, with words, instead of with the things themselves. One of the chief disadvantages of the present arrangement is that when the intern becomes an independent practitioner this convenient arrangement will no longer be available to him. Aid he must have but it must be carefully chosen. At present a large part of the work of contributing services in the hospital is probably unnecessary. This results from the fear of omitting something. It is this fear of omission that impels taking the most minute and extensive histories and the recording of routine elaborate physical examinations, all of which occupy much of the intern's time and leave little opportunity for thinking and independent action. How many interns keep their own records of cases, classify them, think over them, formulate their own concepts and try to rationalize the methods of treatment they employ? Records of cases carefully abstracted, compared and digested are of greater educational value than random experiences, however exciting. To pass through your intern years in a fever of agitation, interested only in obtaining a rapid series of impressions, will add

little to your real experience or improve your training for practice.

When I contrast the long lists of interns and residents in hospitals today with the handful of workers forty years ago, I cannot believe that the intern's life need be more strenuous today. The master word in the hospital, as in the university, is still Work.

Hospital days should be laborious days, but they may be also days of the greatest joy. For the first time you will come into a position of real responsibility for the lives of your patients. It is a cold individual who is not moved by this close contact with those in distress.

During the internship, the hospital should be your home, your workshop and your playground. Shun outside affairs that will complicate your life and disturb concentration on your work, rejoice if you are too poor to own an automobile to carry you from the straight road, avoid the movies, above all avoid entangling affairs of the heart.

A SCIENTIFIC ATTITUDE

The difficulties of maintaining a scientific attitude will be enormously increased once you have left the protecting walls of the hospital. Amid the distractions of domestic life, the competition in professional work, whether you will be able to continue to exercise the scholarly and scientific point of view will depend largely on the use you made of your hospital years. The best guard against retrogression is a constant desire to learn more about the real nature of disease and particularly about some one disease. Some of the most important medical discoveries have been made by men in active practice. The late Dr. Meltzer's example should impress you. For many years he drove about New York every day with a horse and buggy seeing patients and then spent all the time he could in a laboratory, during which period he made important contributions to medicine and physiology. After the Rockefeller Institute was established he went there to work. He died one of the most productive students of disease that our country has had.

The practice of medicine today is far better than it was forty years ago. Some put the blame for the defects on the present method of university education.

In interviewing students I frequently stand amazed by the fluency and skill with which they discuss the most complicated subjects of physiology and pathology and the latest discoveries in medicine. I sometimes wonder, however, whether the facts have been digested and transmuted into wisdom. A doctor should never be ignorant of any fact relating to medicine. But is this cramming scientific education or does it produce scientists?

Let the university heed that it turns out men who have the scientific habit of thought, not

merely men stuffed with facts; however, if the prevailing standards of practice do not fulfil expectations, let us not place the blame for it all on the university. The hospital, the visiting physicians and even the interns and practitioners themselves play parts in the training of good physicians.

We are still far from perfect. The future rests with you. May you continue to be scientifically and critically minded. May you continue to be students as long as you live.

THE ORIGIN OF THE MICROSCOPE

Abridgment of a paper by Dr. Russell L. Haden, published in the Annals of Medical History, January 1939.

The name microscope was suggested by a physician; three of the five great microscopists of the classical period were physicians; one of the first applications of the microscope was the study of medical problems by a physician. The microscope is an application of the science of optics. Books on optics were written by Euclid 300 years before Christ. The first person to mention the actual use of lenses for a definite purpose was the English monk Roger Bacon (1214-1294), who was the initiator of experimental physics.

The first important application of magnifying lenses was in spectacles, which were invented independently in Italy at about 1285 by Salvino degli Armati. An inscription in the church of St. Maria Maggiore in Florence says "Here lies Salvino degli Armati of Florence, inventor of Spectacles. May God pardon his sins. MCCCXVII." Perhaps the allusion to his sins refers to the fact that he kept secret the method of making spectacles.

The possibility of combining lenses for distant vision and for high magnification was discovered later and thus the telescope and compound microscope were invented. The discovery of both the telescope and the microscope belongs to Holland, although the first significant observations with both instruments were made in Italy.

The inventor of the compound microscope seems to have been Zacharias Janssen, who with his father was a spectacle maker in Middelburg in the Dutch province of Zeeland. Janssen discovered in 1590 how to combine convex lenses in a tube to make an instrument for magnifying minute objects and so invented the microscope.

Probably the oldest compound microscope in existence is now in the museum of the Zeeland Scientific Society of Middelburg. Harting, after a careful study, concluded that it is probable that this instrument was made by Janssen. Its greatest magnification is 9 diameters.

One of the most noted of the early microscope makers was Eustachio Divini. A Divini microscope made in 1672 is now in the Museo di Fisica, Padua. Another famous maker of compound microscopes in Italy was Joseph Campani of Bologna, a contemporary of Divini. Little was done in England in the way of making instruments until Robert Hooke in 1665 described his compound microscope. Hooke's microscope initiated a new era in microscopy. He ground his own lenses, constructed his microscope, made observations with it and drew his own remarkable illustrations. A microscope of this pattern used by Hooke is now in the South Kensington Museum in London. The compound microscope remained optically about as Hooke left it for more than a hundred years.

Leeuwenhoek excelled all other early workers in making simple microscopes because of his skill in grinding lenses. He never described his method of grinding. When he died in 1723 he bequeathed to the Royal Society of London a cabinet containing twenty-six microscopes equipped with double convex lenses magnifying from 40 to 160 diameters. Leeuwenhoek at his death had 247 complete microscopes and a total of 419 lenses. His observations were first communicated to the Royal Society of London by letter in 1673.

The most successful of all early simple microscopes is associated with the name of Wilson, although not original with him. This type was first made by Tortona. Wilson's microscope was first made in 1702.

The further development of the compound microscope is due largely to English instrument makers. The next important microscope after Hooke's was made by Marshall in London in 1693 with a magnification up to 100 diameters. Culpepper in 1730 suggested the three pillar type of stand. He also used a concave mirror in the optical axis of the instrument. Focusing was done entirely with the draw tube. The Cuff microscope first made in 1744 includes most of the features of the modern microscope. With this microscope the origin of the compound microscope may be said to end. The later history is one of development.

The most active early investigators with the microscope were members of the Academy of the Lynxes (Accademia di Lincei) in Rome, a scientific society formed in 1603. Among the members were Galileo, Fabio Colonna, a botanist, Francisco Stelluti, a scholar and naturalist, James Faber of Bamberg, resident in Rome as physician of Pope Urban VII, Francisco Fontana of Naples, an astronomer, and Gianbattista della Porta, who probably first suggested combining lenses to make the telescope and microscope (1589). It was Dr. Faber who first suggested the name microscope in a

letter April 13, 1625, to Federigo Cesi, president and a founder of the academy. The word *perspicillum* had previously been used to designate both the telescope and the microscope. Galileo had called his microscope an *occhiale* or *occhialino*. The first plate made with the aid of the compound microscope comprised observations on the bee made by Stelluti about 1630.

The first medical work based on the use of the microscope is the "*Historiarum et observationum medico-physicarum*" by Pierre Borel, published in 1563. His "*Centuria observationum microscopiarum*" records 100 microscopic observations, mainly on minute insects. This is the first book devoted to microscopy. Borel describes how he found ingrowing eyelashes which are invisible to the naked eye and the removal of which relieved conjunctivitis. This was probably the first practical use of the microscope in medicine. Singer suggests that Cesi and Borel should be looked on as the fathers of microscopy.

The first medical illustration with the use of the microscope seems to be in an article in the *Acta Eruditorum* published in 1686 entitled "Description of a New Microscope Made by Joseph Campani and Its Use, communicated by Dr. Schelfstrateus, prefect in the Vatican Library, in a letter dated Rome, June 15, 1686." The illustration shows how the microscope was used in examining a wound.

THE STUDENT HEALTH SERVICE IN A MUNICIPAL UNIVERSITY

Abridgment of an article by Dr. Irvin W. Sander published in the Journal-Lancet, January 1939.

Strictly tax-supported municipal colleges and universities had their beginning in 1837 with the founding of the University of Louisville in Kentucky. At present about 20 per cent of college students in the United States attend municipal tax-supported institutions.

Since the beginning of the first student health service at Amherst in 1860 for the purpose of selecting students physically capable of engaging in athletics and sports, the scope of the service rendered by student health services to the student and to the school has gradually increased. The amount of responsibility assumed varies with the size of the college, its location and the underlying philosophy of its health obligation to the student. The older, larger and privately endowed schools have for the most part developed student health services which provide essentially a complete medical and surgical service for the payment of an annual fee. This broad interpretation of a college's obligation to the student is a form of health insurance.

The objectives of a student health service in a college may be outlined as follows:

1. Sufficient education and training of the student to enable him to care for his health intelligently, through hygienic and proper habits of living. The college health problem is not so much concerned with disease as with the fostering and increasing the strength of people not yet mature, so that a foundation may be laid for long, healthy lives.
2. Protection of the student body from contagious and communicable diseases.
3. Supervision of the sanitary facilities of the school buildings, dormitories and rooming houses.
4. Care of acute illness which requires emergency attention.
5. Physical examinations of all entering students to determine their fitness to participate in required courses of physical education and in the more strenuous elective intercollegiate athletics. Adequate records must be kept of all students and competent interpretation made of the results of the examination.
6. Assisting students in planning their course of study so that it will correlate with their physical and mental abilities. The prevention of overwork on the part of some students is often a necessity. As students seldom pay by their tuition the actual cost of education to the school, this phase of the student health service work may be interpreted as a safeguard of the capital investment of the institution. There is no economy in graduating students who will be shortly compelled to withdraw from the practice of their profession because of illness due to poor supervision of their health habits while attending college.

Fundamentally, the problems of the student health service in a municipal university are the same as in any school of higher education. The students are of the same age group and are no better nor any less prepared for college life than students of other schools. There is, however, less need for the broad administrative development of the health service in the municipal school that is found in the larger endowed school. Many of the city colleges have no dormitories; the few students attending the school from out of town find their own accommodations. As the school district is in a city, these rooming houses will be supervised by the local department of health and should not constitute a health problem to the university.

The fact that most students in a municipal university live at home makes the handling of their health a different problem than in the ordinary school. There will in most cases be a family physician who has cared for the student during previous illnesses and who has a better knowledge of the personal and family history than the student health service physician could hope to learn with his brief contacts. There is no logical reason why the family physician should not continue to care for such a student in the same manner he would have if the student had not enrolled in the university. The same thing may be said of hospitalization of a student.

The few cases of out of town students in the city university who require hospitalization can be cared for in an emergency by sending them

to the city hospital. The school is in this way saved the expense of erecting and maintaining an infirmary for ill students. This will perhaps make the health service less adequate in caring for the students than it might be; but, in general, local facilities will be sufficient to care for the few cases in which the school must assume some degree of emergency responsibility.

Wayne University, operated by the board of education of the city of Detroit, was formed by the union in 1934 of five colleges operated by the board. The Student Health Service was first organized in 1928 as part of the College of Arts and Sciences. Thorough physical examinations are made of all entering students, who are graded in accordance with the results of their physical examinations, and permission is given or withheld for participation in athletic activities. College sports are supervised by the health service and a physician is in attendance at all football games. Since its inception, the Student Health Service has become of increasing value to the students of the university. All physical defects found during the examinations and needing correction are referred to the parents and the family doctor for appropriate care.

The students of Wayne University are not given medical care within the usual meaning of that term. Emergency care is given, but subsequent treatment, if necessary, is referred to the family physician. Athletes competing or trying out for teams representing the university are given medical care to the extent of the facilities of the health service in the event of injury. When such facilities are

inadequate, the student is referred to the family physician or to an appropriate specialist. In circumstances in which it is deemed advisable, the physician's fee is paid by the university. No hospitalization is offered to the students by the health service. A few beds are kept in readiness in the health service building for emergency illness, but the student is kept there only until arrangements are made for his removal to the home or to a hospital if necessary. These beds are available also to students assigned to regular rest periods during the day because of chronic ill health.

Education of the students in matters of health and hygiene is considered the main objective of the Student Health Service of Wayne University. An attempt is made during each personal interview to give authentic advice regarding personal health problems to the end that the student may better understand what can be done and where such aid may be obtained. During the past year 2,080 students were referred to their own doctors or dentists for appropriate care and, when the student had no family physician, aid was given in selecting one appropriate to the need from a list approved by the Wayne County Medical Society. It is felt that the student completes his four years in college with a better understanding of what medical science has to offer and a knowledge of how to utilize that information for his own benefit. He should by that time be on good terms with his family doctor, and every such contact made should be to the benefit of medical science, the physician and the patient.

Correspondence

UNEMPLOYMENT AND THE PUBLIC HEALTH

To the Editor.—I am a senior medical student expecting to graduate in June of next year. From my conversations with classmates I believe that a large percentage of medical students are aware of some rather distinct discrepancies between the things we have been taught in medical school and the things which we observe in the actual practice and interests of the profession.

First, we are taught—and for that matter have come to medical school believing—that the chief obligation and interest of the physician lies in the preservation of the health of the people of his country. One might almost say that the sole social justification for the existence of the medical profession in this country lies in the extent of its execution of its alleged purpose in striving to keep the health of the American people as high as is possible and consistent with our present medical knowledge.

Second, we learn that among the most important causes for a number of important diseases today—tuberculosis, rheumatic fever and others—are the social-economic factors of inadequate living standards.

The entire nation is now in the midst of a critical situation brought about by the merciless cuts in relief

and public works budgets in the face of an economic situation which cannot reabsorb even a small fraction of the unemployed. We are daily faced with a rising incidence of conditions either directly or indirectly resulting from malnutrition and lowered living standards among a sizable percentage of the American people. As this situation continues, I am reasonably certain that we medical students are not alone in questioning the value of, or the justification for, the practice of medicine when the medical means which the physician has at his disposal cannot begin to touch the underlying cause of many of the cases of illness current today.

The medical profession constitutes a rather powerful political pressure group. It seems to me that, if the profession is to be consistent with its teachings and traditions, it is obligated to take up the fight for increased relief budgets and for socially responsible public works programs until a more fundamentally sound "prosperity" can be achieved. Medical care can be of little real value to several million people forced to eat on fifteen cents a day.

JAMES S. MAY, Rush 1940.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

The Victor C. Vaughan Dormitory at Ann Arbor

The Victor C. Vaughan House, the new dormitory for medical students at the University of Michigan, Ann Arbor, was opened for use at the beginning of the new academic year. One of a group of dormitories built recently at Ann Arbor, it offers accommodations for 139 medical students. The staff of the Victor C. Vaughan House includes a resident adviser who acts as an overseer of student life, three assistant resident advisers and a director-dietitian. The resident adviser is Dr. Henry S. Emerson, instructor in anatomy. The dormitory was named in honor of Dr. Victor C. Vaughan, who was for many years dean of the University of Michigan Medical School.

Beginning a New Year at Jefferson

The 115th annual session at Jefferson Medical College of Philadelphia was inaugurated September 20. Robert P. Hooper, president of the board of trustees, presided and the introductory lecture was delivered by Dr. David M. Davis, professor of genito-urinary surgery, on "Self-Reliance and the Medical Curriculum." The total enrolment is 498, of which number 145 are new students (135 admissions to the first year class and ten admissions to the third year class). The members of the first year class were prepared for medical study in sixty different institutions. Thirty-two states, Puerto Rico, Hawaii, Persia and Korea are represented. Announcement was made of the election of Dr. James R. Martin as James Edwards professor of orthopedic surgery, succeeding Dr. J. Torrance Rugh, who was made emeritus professor.

Medical Students' Musical Fraternity

The musical group at the University of Illinois College of Medicine in Chicago was first organized in 1931. After a few years this group was founded as a musical fraternity, Phi Mu Phi. The *Illini Scope* claims that this organization is the only musical organization in a medical school in the United States. A medical school in another state has requested permission to inaugurate the Beta chapter of Phi Mu Phi.

Family Doctors and Scholarships at Tufts

The award of four Commonwealth Fund scholarships to incoming students of Tufts College Medical School, Boston, was announced September 20 by Dr. A. Warren Stearns, dean. These provide \$1,000 a year to one resident of each of the four northern New England states, on condition that the recipient agrees to practice in a rural community in his state for at least three years following two years' internship after graduation. The scholarships were awarded to George L. Cushman, Medford, Mass.; Eugene H. Wozmak, East Jaffrey, N. H.; Charles R. Blackburn, Brattleboro, Vt., and Stanley W. Staples, Gardiner, Maine.

The Charles P. Thayer Scholarship and the Elizabeth A. Riley Scholarship for second-year women students were awarded respectively to Miss Victoria L. Maxwell, Mamaroneck, N. Y., and Miss Winifred Sanborn, Boscawen, N. H.

Tufts College Medical School, which is one of three medical schools in the country chosen as recipients of the Commonwealth Fund scholarships, draws its stu-

dent body largely from the colleges of New England. The announcement says that of 6,000 physicians trained in New England and settled in New England communities since 1900, one in three is a Tufts graduate.

Louisiana's Graduating Class

Of the sixty-two fourth year students of the School of Medicine of Louisiana State University who received the Bachelor of Medicine degree at the university commencement in Baton Rouge May 29, forty-six were from Louisiana. Twenty-seven already had the Bachelor of Science degree, eight the Bachelor of Arts degree, one the degree of Doctor of Dental Surgery and another the Doctor of Philosophy degree. The five students in the class who made the highest grades are, in the order of their standing, Joseph D. Lea, New Orleans; Samuel Zurik, Brooklyn; Eustace V. Chauvin Jr., Lafayette, La.; Robert B. Morrison, Austin, Texas, and Melville Rosenbusch, Richmond Hill, N. Y.

Loans to Students at Harvard

Funds have been established at Harvard Medical School, Boston, to which students in need of money may make applications for loans. Amounts up to \$400 may be loaned to a student during any one year and up to a total of \$1,000 during the course. Application should be made by May 15, but in an emergency it may be made at other times. Notes are payable two years after graduation and 5 per cent interest is charged. Loans are made to students in the second, third and fourth year classes whose records are sufficiently creditable to make it probable that they will remain in the school and will be able to repay the loan at the time arranged for. Recent matriculants may apply for their loans only in their second half year. Loans are rarely made to married students. Among the various loan funds are the David L. Edsall Revolving Loan Fund, the Charles William Eliot Loan Fund, the John Foster Fund, the Loan Fund of the Medical Class of 1879. Application should be made at the office of the dean of the medical school.

Harvard also has a great many scholarships to offer in the way of rewarding and aiding medical students. Most of these scholarships are open only to students who are members of the school at the time of application; however, in order to make it possible for young men of great ability and promise to come to Harvard Medical School, one or two Harvard Medical School National Scholarships are offered to incoming members of the first year class. The stipend carried by these two scholarships is sufficiently large, if necessary, to meet all the student's essential expenses. Successful applicants who maintain a high honor record at the school will continue to hold these scholarships throughout the course at the medical school. These scholarships are made possible by gifts from Edward S. Harkness and Dr. Daniel F. Jones. Direct application for these scholarships cannot be made, since all accepted first year students are considered candidates and the awards are made without reference to financial circumstances.

Harvard has available also fellowships for the purpose of aiding students, graduates or teachers in research or postgraduate study. Applications concerning all the foregoing should be made to the office of the dean, Harvard Medical School.

Medical Murals Presented to University of California

Murals depicting the history of California medicine were presented to the University of California at a special ceremony recently in the university hospital. The murals occupy all the free portion of the circular wall in Toland Hall above the demonstration pit. One wall shows the development of medicine in northern California and the other in southern California. The earliest Indians are seen emerging from their sweat houses, or being worked over by the medicine man. Gold rush medicine is the subject of a mural in the central background. Dr. Don Pablo Soler, Spanish surgeon of the late eighteenth century, is seen attending an Indian. The transition from these early crude forms of medical attention to the scientific procedures of today is skilfully made by the artist. Another central panel shows the first hospital of California, a crude shelter put up at San Diego in 1789 to succor members of the Portola expedition. The incident of James Ohio Pattie, old California trapper, vaccinating a number of early Californians against smallpox is also shown.

Dartmouth Personal

Donald deForest Bauer, Brooklyn, a sophomore at Dartmouth Medical School, Hanover, N. H., has been awarded a Mellville Cramer Foundation Fellowship and will study genetics at McGill University, Montreal, where he will be a candidate for a doctorate in both medicine and philosophy. Mr. Bauer is the son of Dr. John L. Bauer.

Loan Funds at Emory University

Emory University, Atlanta, Ga., has a number of loan funds which are used to assist worthy students, about which information may be obtained from the dean of men. It is difficult, however, to secure loan funds for students of medicine in the university except during the junior and senior years, on account of the length of time necessary for medical students to remain in school. The demand for assistance is greater than can be met by these funds, and a student who is able to do so should make previous arrangements for financial aid. University bills for tuition, fees and dormitory are payable by the quarter in advance. There is a matriculation fee of \$5, payable only once. A student activities fee of \$4.50 is collected quarterly, and the charge for tuition and fees is \$112.50 a quarter. Each student must keep on deposit a damage deposit fee of \$5 to guarantee against loss or damage of university property entrusted to him. Each student must provide himself with a microscope.

The charge for a single room in Dobbs Hall by the quarter is \$30. Meals may be obtained in a cafeteria on the campus at from \$17 to \$25 a month.

Loan Funds at Marquette

The Father Noonan Student Aid Society administers a loan fund which is available only to seniors. The Mary Connor Student Loan Fund was established by the Wisconsin Council of Catholic Women for the assistance of women students and is ordinarily available only to juniors and seniors. Information may be obtained regarding these funds from the dean of men and the dean of women respectively. The university has a residence hall for women students from out of town known as the Alumni House and also a social center for women students known as Drexel Lodge, the latter providing study, rest and recreation rooms and facilities for serving luncheons. The Marquette Union is available for male students of the

entire university. It provides a lounge, billiard room, banquet hall, refreshment counter, cafeteria and reception room. The union aims to foster genuine democracy among the students, to develop their sense of responsibility, to promote their powers of self government and to cultivate the social factors of harmony and refinement.

Estimate of Expenses at Marquette

Following is an estimate of about the lowest figures on the expenses for the school year at Marquette University School of Medicine, Milwaukee:

Tuition and fees.....	\$450
Board and room.....	270
Laundry	50
Books and stationery.....	75
Microscope, per year (if purchased on instalment basis)	35
Incidentals	30
Total	\$910

Portrait of Irvin Abell

At the graduation banquet of the University of Louisville School of Medicine, Louisville, Ky., the class of 1939 presented to the school an oil painting of Dr. Irvin Abell. Dr. Osear O. Miller presented the painting, which was received by the dean, Dr. John W. Moore.

Student Health Service at Indiana

With the opening of the 1939-1940 school year, a student health and medical service was established at Indiana University, Indianapolis. Dr. Willis D. Gatch, dean of the Indiana University School of Medicine, has been named director of the program. The service will provide clinical facilities for all students in the university with attendant physicians and nurses, twenty-four hour provision for emergency calls, an x-ray laboratory, beds for observation cases and hospitalization.

Scholarship Available for Freshmen at Alabama

The local chapter of Phi Beta Pi medical fraternity has established at the University of Alabama School of Medicine, University, Ala., an annual scholarship of \$90 to be awarded to some worthy freshman who has matriculated by May 1 for the next regular session of the school of medicine. A committee of Professors Carmichael, Foley, Goss, Graves, Hunt, Jeller and McBurney was nominated to make the award. For guidance of the committee the donors made the following statement:

In making the award, it is the sentiment of the donors that the previous scholastic record and other qualifications of any student shall have been such that the award would be granted to a student who gave promise of a successful career in medicine; and finally, other things being equal, the award should preferably be given to a student, man or woman, who needed financial aid.

Research Assistantships at Louisville

Research assistantships of \$135 each are allotted annually to seven students at the University of Louisville School of Medicine, Louisville, Ky., who distinguish themselves in research. Preference is given to candidates for graduate degrees.

Expenses at Vanderbilt

The average annual expenses of a student at Vanderbilt University School of Medicine, Nashville, Tenn., exclusive of clothes and incidentals, are estimated at from \$800 to \$1,000. Among the items the sum is the tuition fee for the year of

fee of \$10, a diploma fee of \$5, a fee for the support of the Student Union of \$5 and, for the fourth year students, a rental charge of \$2 for academic hoods at commencement. Each student is required to possess a standard microscope, but to aid first year students in purchasing one the school will advance three fourths of the purchase price, to be repaid in three equal instalments at one, two and three years after the date of purchase. The necessary books cost about \$50 a year. All students are required to provide themselves with hemocytometers and hemoglobinometers before the beginning of the second trimester of the second year.

Tests for Premedical Students at Minnesota

The Minnesota Medical Aptitude, the Strong Vocational Interest, and the Sophomore Culture Tests must be taken at the end of the second premedical year or in the first quarter of the third year. Students at the University of Minnesota may take these tests on the campus at a time to be announced in the official bulletin. Students in other colleges and universities should communicate with the University Testing Bureau to make arrangements for taking these tests. Fees are payable by the applicant.

The National Medical Aptitude Test is given in December of each year at the various universities and colleges of the country. It is best taken during the second or sophomore year in college.

Scholarships and Medals at Vanderbilt University

A Founder's Medal is awarded to the student in the graduating class of Vanderbilt University School of Medicine, Nashville, Tenn., who has attained the highest average standing in scholarship throughout the four consecutive years of study.

The Commonwealth Fund provides an annual grant as a scholarship fund for deserving medical students. The terms require that a student who receives such consideration shall agree to practice as much as three years in a rural area in Tennessee after graduation and after having served an internship of not less than two years. These scholarships may be renewed for each of the four years of medical study, but only bona fide residents and natives of Tennessee are eligible. Application blanks, which may be obtained from the registrar at the school of medicine, should be filed prior to March 1.

The Beauchamp Scholarship is awarded to the student showing the greatest progress in the department of neurology and psychiatry and who is otherwise worthy and deserving.

The Dr. Ben Witt Key Annual Award, amounting to \$500, is made to the fourth year student who is among the five highest in scholarship and judged by the faculty to be outstanding in scientific ability, in character and in personality.

Internships in Baylor Hospital

Each year thirteen members of the graduating class of Baylor University College of Medicine, Dallas, are awarded internships in Baylor Hospital on their scholarship standing and personal fitness. This is a one year internship beginning July 1 and, according to the official bulletin of the university, offers exceptional opportunities for a broad clinical training in the treatment of a great variety of diseases. The 400 bed Parkland Hospital, which is jointly controlled by the city and county of Dallas, offers a combination graduated service of internship and residency extending over a period of two years.

The Opening of School at Ann Arbor

The ninetieth annual opening of the University of Michigan Medical School, Ann Arbor, was held in the School of Graduate Studies, September 25, on which occasion the president of the University of Michigan, Dr. Alexander G. Ruthven, introduced Dr. Francis E. Seneer, of Chicago, who spoke on "Some Phases of Medical Education and Practice." A graduate of the University of Michigan Medical School, Dr. Seneer has been head of the department of dermatology at the University of Illinois College of Medicine, Chicago, since 1925, and during the past year was president of the American Dermatological Society. Following the convocation address, Dr. Seneer was granted the honorary degree of Master of Arts. At this time, also, the Sternberg Medal was awarded to Dr. Malcolm Block, of the class of 1939, for outstanding work in medical research and high scholarship.

Interns' Organization

The annual meeting of past and present interns of the San Diego County General Hospital was attended June 22 at the Emerald Hills Country Club by thirty-five physicians. Dr. Alfred J. Cooper acted as chairman, and a permanent organization was formed with Dr. Alexander M. Lesem, president. An appropriate greeting was voted for the incoming interns.

Transfer of Students from North Carolina

Only the first two years of the medical course are given at the University of North Carolina School of Medicine, Chapel Hill. It is necessary for the students to go elsewhere for the remainder of their studies. Following are the transfers which the students have made for the year beginning in September 1939:

Jesse Appel, Brooklyn, to New York University College of Medicine, New York.

Ralph M. Bell, Mooresville, N. C., to Jefferson Medical College of Philadelphia.

Daniel H. Buchanan, Chapel Hill, N. C., to Harvard Medical School, Boston.

Jesse B. Caldwell, Cramerton, N. C., to McGill University Faculty of Medicine, Montreal.

Henry T. Clark, Scotland Neck, N. C., to the University of Rochester School of Medicine, Rochester, N. Y.

Charles E. Cloninger, Claremont, N. C., to the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore.

Joseph B. Crawford, Goldsboro, N. C., to Jefferson Medical College of Philadelphia.

Alfred M. Elwell, Camden, N. J., to the University of Pennsylvania School of Medicine, Philadelphia.

Benjamin F. Fortune, Greensboro, N. C., to Jefferson Medical College of Philadelphia.

Eugene F. Hamer, McColl, N. C., to the Medical College of the State of South Carolina, Charleston.

Pearl Huffman, Morganton, N. C., to the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore.

Gilmer Mcbane, Chapel Hill, N. C., to Harvard Medical School, Boston.

Ralph S. Morgan, Penland, N. C., to Rush Medical College, Chicago.

Max M. Novich, Newark, N. J., to the University of Louisville School of Medicine, Louisville, Ky.

Irene Phrydas, Greensboro, N. C., to the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore.

Edwin A. Rasberry, Snow Hill, N. C., to the University of Pennsylvania School of Medicine, Philadelphia.

Maek Simmons, Chapel Hill, N. C., to the Medical College of the State of South Carolina, Charleston.

Emmet R. Spicer, Goldsboro, N. C., to Cornell University Medical College, New York.

Robert L. Stricker, Asheville, N. C., to the University of Pennsylvania School of Medicine, Philadelphia.

Edmund R. Taylor, Chapel Hill, N. C., to Johns Hopkins University School of Medicine, Baltimore.

Thomas G. Thurston, Taylorsville, N. C., to Harvard Medical School, Boston.

James L. Wardlaw Jr., Calypso, N. C., to New York University College of Medicine, New York.

Samuel B. Willard, Doylestown, Pa., to Long Island College of Medicine, Brooklyn.

Milton H. Yudell, New York, to Rush Medical College, Chicago.

RIBOFLAVIN DEFICIENCY IN HUMAN SUBJECTS

V. P. SYDENSTRICKER, M.D.

L. E. GEESLIN, M.D.

C. M. TEMPLETON, M.D.

AND

J. W. WEAVER, M.D.

AUGUSTA, GA.

The possible relation of riboflavin deficiency to certain manifestations of human pellagra has been of interest to investigators of various deficiency diseases for a number of years. During 1935 and 1936 at least four groups of observers¹ treated small groups of pellagrins with relatively minute doses of riboflavin with no evidence of curative effect. Our own experience with four patients treated with 3 mg. of lactoflavin a day for five days was entirely negative. Sebrell, Hunt and Onstott² observed no improvement in dogs with experimental blacktongue given relatively large doses of riboflavin by mouth. Nevertheless the close similarity of the mode of death of dogs with experimental riboflavin deficiency with that in fatal human pellagra and the constant finding of extreme fatty degeneration of the liver in the two conditions seemed to point to some significant relation.

No clinical sign of human riboflavin deficiency had been recognized until Sebrell and Butler³ in 1938 called attention to the incidence of "cheilitis" in a number of patients maintained under experimental conditions on a diet poor in riboflavin; this condition was cured by riboflavin. The "cheilitis" described by Sebrell and Butler occurs frequently in endemic pellagra and has commonly been considered an accessory sign of the pellagrous syndrome. Stannus⁴ many years ago described it as "marginal stomatitis." The lesions consist of redness, desquamation and finally ulceration of the lips at the mucocutaneous junction with fissures or "rhagades" at the corners of the mouth; either or both may be present. A number of Sebrell's experimental subjects presented these phenomena before any frank signs of pellagra were evident. The relation of

these epithelial lesions to the dermatitis of pellagra is of considerable interest, particularly since it has been the common experience that "cheilitis" and dermatitis heal slowly under nicotinic acid therapy of pellagra while treatment with yeast or liver extract causes rapid involution. It has also been observed that cheilitis may develop while oral and neurologic manifestations of pellagra are being cured with nicotinic acid.⁵ In some instances cure of rhagades has been observed in patients treated with nicotinic acid alone,⁵ but here the question of increased appetite with consumption of large amounts of "pellagra-producing" food containing some riboflavin must be considered. Spies and the Vilters,⁶ thought that pellagrous dermatitis in patients treated with nicotinic acid healed more promptly after the administration of large doses of riboflavin.

During the past three months six patients have been observed who showed evidence of possible riboflavin deficiency; five of these had definite signs of pellagra as well. Patient 2 was so ill that it was not considered justifiable to hold her under experimental conditions; patient 5 had diabetes and was in urgent need of control, so her diet was that required for regulation of her diabetes. The other four patients were kept on our standard pellagra-producing diet during the period of experimental therapy. Riboflavin used in treatment was the synthetic crystalline product furnished by Merck & Co., Inc., and "Lactoflavin" for injection was furnished by the Winthrop Chemical Company. An extract of liver prepared for intravenous use but lacking in hemopoietic activity was furnished by Parke, Davis & Co.

REPORT OF CASES

CASE 1.—J. A. M., a white man aged 34, was admitted Dec. 30, 1938, in severe alcoholic excitement. He was known to have been on a prolonged debauch and to have eaten little for about three weeks. There was a fine sealy dermatitis of the nasomalar grooves and alae of the nose as well as of the chin. There were deep radiating fissures at the corners of the mouth, and the lips were red and excoriated along the line of apposition. The tongue was typical of pellagra. There was slight brownish dermatitis of the hands and elbows. General physical examination as well as routine laboratory determinations showed nothing of significance. The gastric contents after histamine showed 20 degrees free hydrochloric acid and 30 degrees total acidity. He was maintained largely on dextrose solutions given intravenously and liquids by mouth for ten days, during which there was slight increase in the labial lesions and glossitis. There was no diarrhea. A pellagra-producing diet was begun Jan. 10, 1939, and on January 11, 12 and 13 the "nonhemopoietic" liver extract was given, 40 cc. intravenously each day. No effect on the glossitis or cheilitis was evident after six days. Lactoflavin was then administered

intramuscularly, 3 mg. a day from the 19th through the 24th. January 23 there was definite evidence of healing of the lips. This continued slowly and was complete on the 30th. During the same time the scaly dermatitis of the nose and chin resolved. Later treatment with nicotinic acid caused rapid cure of the glossitis.

CASE 2.—R. B., a white woman aged 38, was admitted Jan. 3, 1939, with a diagnosis of severe endemic pellagra. She

Fig. 1 (case 3).—Tongue on admission.

was emaciated, disoriented and slightly febrile and had severe diarrhea. There was marked fine scaly dermatitis of the nose and malar eminences without erythema. The lips showed extreme redness and excoriation along the line of closure, and there were deep radiating fissures at the corners. The gums, oral mucosa and tongue were fiery red with much superficial ulceration and gray exudate, the pharynx and visible portions of the larynx showed similar lesions and the patient was aphonic from involvement of the vocal cords. General physical examination revealed nothing noteworthy. The vagina was intensely red with much seropurulent discharge. Dermatitis of the neck, hands and feet was absent. The blood showed 10 Gm. of hemoglobin per hundred cubic centimeters, 4,100,000 erythrocytes and 7,600 leukocytes per cubic millimeter. The Wassermann reaction was strongly positive. Other laboratory examinations were not significant. It was not possible to examine the gastric contents on account of the extreme sensitiveness of the inflamed pharynx. The patient was given a soft pellagra-curative diet without yeast, and nicotinic acid was administered intravenously, 300 mg. a day from January 4 to 7; thereafter it was given by mouth, 75 mg. a day. There was the usual dramatic response of the glossitis, stomatitis and diarrhea; all were cured on the third day of treatment, and on this day the mental state seemed quite normal. The patient ate of

Fig. 2.—(case 3).—Dermatitis of hands on admission.

the curative diet greedily after the first day of treatment. The lips healed somewhat more slowly than the buccal mucosa, but on the fifth day of treatment cheilitis and rhagades were cured.

CASE 3.—F. P., a white man aged 54, was admitted Feb. 9, 1939, with a diagnosis of relapse of chronic pellagra; he had been seen on four previous admissions with severe pellagrous lesions. At this time there was slight branny desquamation of the nose and malar eminences, the lips and buccal mucosa were of normal color, there were no fissures at the corners of

the mouth and the tongue was of normal color and texture (fig. 1). The hands showed a bright red "dry" dermatitis with marked desquamation (fig. 2) quite different from the usual vesicular and bullous lesions present on previous admissions and the genitalia and feet were free from dermatitis. General physical examination was negative. The blood contained 11 Gm. of hemoglobin per hundred cubic centimeters and 3,000,000 red cells and 11,000 white cells per cubic millimeter. There was total achlorhydria after histamine. Other laboratory examinations were not significant. This man was of particular interest because he had been the subject of numerous therapeutic experiments and was a very labile pellagrin in whom relapse could be produced quite regularly by maintenance on dextrose and water or on a "maize diet" for five or six days. His

Fig. 3 (case 3).—Hands after treatment with riboflavin.

Fig. 4 (case 4).—Lesions of lips and nares before treatment.

present dermatitis was quite different from that seen on previous admissions; the usual severe stomatitis and glossitis were absent and he did not have diarrhea. He was given the basal pellagra-producing diet and riboflavin was administered subcutaneously, 50 mg. February 12, 13 and 14. No other treatment was used and from February 15 the left hand was exposed to an infrared lamp for twenty minutes twice each day. On February 16 there was definite blanching of the hands; this was progressive and by February 24 the skin was of normal color, though there was still some desquamation. In the opinion of various observers the hand exposed to heat healed somewhat more rapidly than did the other. February 27 an attempt to produce relapse was made by putting the patient on a dextrose and water diet; this was continued for five days with no effect (fig. 3). A "maize diet" consisting of 500 Gm. of cornmeal mush and syrup as desired was then substituted for dextrose and water and continued for four days without producing any sign or symptom of pellagra. The experiment was then terminated.

CASE 4.—L. J., a Negro girl aged 17, was seen Feb. 18, 1939, on account of a "sore mouth" which had developed during hospitalization subsequent to an arthroplasty of the left hip joint. For about three weeks after the operation she had refused regular ward diet and had eaten hardly anything except white bread and syrup, corn bread and syrup and hominy with gravy. She was excellently nourished and developed, afebrile and free from gastrointestinal disturbances. The palpebral and scleral conjunctivas were very red, there was a small amount of serous exudate from the conjunctival sacs, and photophobia was extreme. There was no evidence of iritis. The lips were intensely red, almost denuded, with deep fissures in the vermillion and slight fissures at the corners; the upper lip showed an oozing moist dermatitis; there was a deep fissure

Fig. 5 (case 4).—Lips and nares after treatment with riboflavin.

Fig. 6 (case 5).—Lesions of lips and corners of mouth on admission.

at the junction of the nasal septum and lip, and the septum and lower portions of the alae showed dermatitis similar to that on the upper lip. The skin elsewhere was of excellent texture. The tongue and buccal mucosa showed nothing abnormal. General physical examination and routine laboratory procedures were not significant. Cultures from the lips and nose showed no unusual bacteria and no fungi (fig. 4). The patient was put on a pellagra-producing diet, which she ate well, and on February 19 riboflavin was given by mouth, 30 mg. in doses of 10 mg. three times a day; this was continued until February 23. During these five days there was some improvement in the lips but none in the nasal lesion; the amount of riboflavin was increased to 60 mg. a day on February 24, and this dose was continued until February 26, at which time the lips were cured and the deep fissure at the base of the nasal septum was almost healed. Two days after treatment was discontinued there was a rapid recurrence of cheilitis and the nasal fissure reopened. On March 1 and 2

riboflavin was given hypodermically in doses of 10 mg. once a day, and by March 4 the lesions were again healed; on this occasion there was marked improvement in conjunctivitis and photophobia. On March 9 a second relapse occurred, the lips nose and conjunctivas being quite as much affected as at first. On this day 20 mg. of riboflavin was given intravenously. From this time on there was rapid healing of the lips and nose with disappearance of conjunctivitis and photophobia. On

Fig. 7 (case 5).—Lips after treatment with riboflavin.

March 15 no abnormality of the lips could be seen, the nasolabial fissure was healed and the eyes were normal (fig. 5). The patient was then given a regular diet and has remained well.

CASE 5.—M. W., a white woman aged 58, was admitted March 1, 1939, with the diagnosis of diabetes mellitus. She was slightly obese, somewhat pale and had slight edema of the feet. There were deep fissures at the corners of the mouth, and the lips were red and slightly excoriated along the line of apposition (fig. 6). The tongue was bright red, atrophic and fissured. General physical examination showed cardiac hypertrophy, severe hypertension and moderate enlargement of the liver. There was vaginitis with some seropurulent discharge. The fasting blood sugar was 330 mg. per hundred cubic centi-

Fig. 8 (case 6).—Lesions of corners of mouth which developed during treatment with nicotinic acid.

meters, and 11 Gm. of dextrose was excreted in the first twenty-four hour collection of urine. She was given a diet containing 50 Gm. of protein, 50 Gm. of fat and 150 Gm. of carbohydrate, and 10 units of protamine zinc insulin was administered each morning. On the third day the lips were healed and the fissures at the corners of the mouth were dry and well covered with epithelium. The original amount of protamine zinc insulin was found inadequate and the dose was increased on March 8

to 30 units. On March 10 the fissures at the corners of the mouth reopened and were quite painful; the tongue had remained red and fissured. On March 11 riboflavin was given intravenously, 10 mg. in 200 cc. of physiologic solution of sodium chloride, and on March 12, 25 mg. was administered by the same route. The lips healed during the ensuing three days and the patient felt much better; no change was noted in the tongue (fig. 7). During this time the dose of insulin had been increased to control glycosuria and hyperglycemia until 50 units was being given daily. March 19 there was a sudden recurrence of the cheilitis and painful fissures at the corners of the mouth. Riboflavin was given by mouth in doses of 20 mg. a day for five days, and again the lips healed, though small fissures persisted in the right corner of the mouth. Nicotinic acid was then started, 25 mg. four times a day. Glossitis, which had persisted, was healed on the third day of treatment, but slight excoriation persists at the corners of the mouth.

CASE 6.—L. H., a white woman aged 68, was admitted March 8, 1939, with the diagnosis of chronic endemic pellagra. She was emaciated, pale and slightly disoriented. There was slight scaly dermatitis of the nose and nasolabial folds, small fissures were present at the corners of the mouth, the lips seemed normal and the tongue was bright red and atrophic. The skin over the dorsal surfaces of the hands was atrophic but no dermatitis was present. General physical examination showed arteriosclerosis and moderate hypertension, moderate cardiac hypertrophy and the residua of a left hemiplegia. The blood showed 9 Gm. of hemoglobin per hundred cubic centimeters, 3,800,000 red cells and 8,400 white cells per cubic millimeter. The gastric contents were achlorhydric. The patient had been seen on several occasions with various manifestations of pellagra. She was given a pellagra-producing diet, and nicotinic acid was administered intravenously, 100 mg. a day from the day of admission until March 20. Disorientation and glossitis were absent on the third day of treatment but the fissures at the corners of the mouth grew rapidly worse and by March 11 were so painful as to interfere with eating (fig. 8). Ten mg. of riboflavin was given subcutaneously on March 11, and because no effect was observed 50 mg. was given by the same route on March 13. On the second day there was much improvement in the oral fissures but by March 17 they had recurred and were painful. Riboflavin was then given by mouth, 20 mg. daily from March 17 to March 23, with some improvement. The fissures became dry and less painful but did not heal. March 20 a soft diet was given and oral administration of 100 mg. of nicotinic acid was substituted for intravenous injection. During the nine days no change has occurred in the fissures at the corners of the mouth, though there has been considerable improvement in the patient's condition.

COMMENT

Five patients who presented lesions corresponding with those described by Sebrell and Butler as being due to riboflavin deficiency have been observed; another with atypical dermatitis of the hands is included in this report. Five of these patients either showed evidences of pellagra or were known to be chronic pellagrins. Patient 2 was cured of cheilitis as well as of pellagrous lesions while under treatment with nicotinic acid and an ample diet. It seems likely that adequate intake of food containing ample amounts of riboflavin explains her recovery. Patient 4 had no sign or symptom of pellagra but showed severe cheilitis and conjunctivitis; she recovered under riboflavin, given by various routes, and twice relapsed soon after treatment was discontinued. Patient 3, who was a known pellagrins, showed no definite signs of pellagra but had an atypical dermatitis of the hands, which was apparently cured by large doses of riboflavin. Attempts to produce pellagra by severe dietary restriction were later unsuccessful. The other three patients showed much improvement of cheilitis and fissures in the corners of the mouth under riboflavin therapy, though there was a tendency to rapid relapse when treatment was

stopped. Large doses of riboflavin were much more effective in all cases and parenteral administration seemed much more efficient than oral. In every instance response to riboflavin was relatively slow, and in the presence of an inadequate diet nicotinic acid given concurrently seemed to have no adjuvant effect. One patient developed cheilitis while under treatment with nicotinic acid.

Particular interest was aroused by cases 3 and 4, in which dermatitis, cheilitis and conjunctivitis seemed to be cured by riboflavin.

A NEW METHOD OF TREATMENT OF SUBACUTE BACTERIAL ENDOCARDITIS

USING SULFAPYRIDINE AND HEPARIN IN COMBINATION: PRELIMINARY REPORT

SAUL R. KELSON, M.D.

WITH THE ASSISTANCE OF
PAUL D. WHITE, M.D.

BOSTON

Analysis of 250 cases of subacute bacterial endocarditis with positive blood cultures for alpha (viridans) and, rarely, gamma streptococci in Boston hospitals¹ stressed the ineffectiveness of all varieties of therapy prior to the new chemotherapeutic drugs. Sulfanilamide, used in twenty-four cases, and protosil, used in five, temporarily improved a few; used in four cases, sulfapyridine, although not curative, appeared far more effective. Data that we have collected from other clinics and from one case report concerning sixty-six well studied cases in which intensive treatment was given with sulfapyridine confirm our experience that in most instances the drug lowers the temperature and sterilizes the blood stream but that these effects pass off in from a few days to a month or, rarely, more. Only in one reported case,² in which the blood cultures were positive for gonococcus and a nonhemolytic anaerobic streptococcus, was there a recovery; the disease followed its usual course in the other sixty-five.

Blood of patients with subacute bacterial endocarditis usually has a high titer of antibodies for the organisms;³ despite this fact, these bacteria will grow in the serum, but they die quickly, even in normal serum, when leukocytes are present.⁴ The streptococci lie as a rule near the periphery of the vegetation, a mass chiefly of fibrin, an ideal culture medium and protective barrier, and of platelets. Polymorphonuclear leukocytes are scarce or absent in the vegetation.⁵ At its base, fibrosis is a nearly constant finding.

By present means it appears impossible to increase the number of phagocytes and draw them into contact with the bacteria, to dissolve the vegetations or to induce granulation within them. One can attempt, however, to prevent further thrombotic deposition on their surface in order to (1) restrict the nidus and culture

medium for bacterial growth, (2) prevent embolism from the freeing of fresh thrombus, and (3) check the growth of the vegetations so that proliferating fibroblasts may fill in the areas thus limited.

These considerations have led us to treat the disease not only with sulfapyridine, for its bacteriostatic and perhaps bactericidal action,⁶ but also with an anticoagulant, crystalline heparin,⁷ which had been shown effective and in other conditions nontoxic, was chosen.⁸

METHOD

The contents of a 10 cc. vial of heparin (10,000 units) is added to 500 cc. of physiologic solution of sodium chloride, and such a solution is given by uninterrupted intravenous drip day and night for fourteen days. The rate of flow (usually from 15 to 25 drops a minute) is carefully regulated to maintain, as well as possible, the venous clotting time (normally below twenty minutes) at approximately one hour. Clotting time is measured before treatment, twice or more the first day and then at least daily by the five tube method of Lee and White.⁹ Heparin is begun from four to seven days after sulfapyridine has been started, when nausea and vomiting have subsided and before "escape" from its effects has occurred. From 4 to 6 Gm. of sulfapyridine (with desired blood levels of 5 mg. per hundred cubic centimeters or more) is given daily by mouth before and during the use of heparin and for one week afterward—a total of about four weeks. Blood transfusions are given if there is anemia of 3,500,000 red blood cells or below. Persisting infections (including this one¹) predispose to vitamin C deficiency,¹⁰ which interferes with fibrous repair;¹¹ all patients, therefore, are saturated with 200 mg. of ascorbic acid by mouth four times a day for three days and continued on 100 mg. a day. Other added vitamins and iron are not essential to the therapy.

RESULTS

Six of our patients with subacute bacterial (*Streptococcus viridans*) endocarditis and one patient with the rarer condition of acute bacterial endocarditis caused by the same organism have received the combination of sulfapyridine and heparin. Each had had four or more positive blood cultures. They were treated in the following order:

CASE 1.—F. G., a man aged 21 with advanced disease complicating patency of the ductus arteriosus, had severe recurrent pulmonary infarction after three days of heparin (April 1939) and both drugs were omitted. He died two weeks later.

CASE 2.—E. S., a man aged 22 with a history of five attacks of rheumatic fever, resulting in great heart damage, had been ill two and one-half weeks with characteristic manifestations of subacute bacterial endocarditis. Because of a red tender joint, migratory arthralgia, prolonged auriculoventricular conduction and epistaxes, concurrent rheumatic fever was diag-

nosed¹² and further indicated by later onset of auricular fibrillation following rheumatic pleuritis. The rectal temperature (104.6 F.) fell sharply on administration of sulfapyridine (April 1939); cultures became negative. He was given two transfusions. After receiving a total of 260 cc. of heparin in fourteen days he gained strength and weight, and his temperature stayed under 100 F. for forty-five days (except for one rise of 0.5 degree F.), then rose for three days with the pleuritis. Since then, signs of rheumatic infection have recurred, and he has been kept in bed since fibrillation appeared, with persistent congestive heart failure. He has shown no evidence of bacterial endocarditis, however, since shortly after the specific treatment was stopped; since sulfapyridine has been omitted (May 19) nineteen consecutive blood cultures have been negative.^{12a}

CASE 3.—A. C., a woman aged 23 with rheumatic fever at 9 years and a slight mitral lesion, had a slowly progressing bacterial endocarditis for six months, with an oral temperature to 102 F. and splenic and cerebral embolism. Blood cultures became negative on administration of sulfapyridine (April 1939). She received 290 cc. of heparin in fourteen days. Since sulfapyridine has been omitted (May 26) all blood cultures have been negative, she has gained strength and weight (26½ pounds [12 Kg.] in three months) and has shown no evidence of the disease. She has walked since June 14, is active and at work and has no complaints.

CASE 4.—M. S., a girl aged 19 years, with three attacks of rheumatic fever and severe heart damage, had been ill three weeks. After two transfusions, sulfapyridine was begun (June 1939); the rectal temperature fell sharply from 102-104 to 100 F. or less but rose after eight days. Cultures remained positive. Heparin was omitted after forty hours because of sudden headache, vertigo and amblyopia. These conditions cleared, but five days later, after thirteen hours of heparin, she had a chill and fever and died. Autopsy showed large occipital and subdural hematomas. These were probably embolic and occurred, we believe, spontaneously, though the drug very likely increased the hemorrhage and hastened death.

CASE 5.—E. L., a man aged 41 with rheumatic aortic and mitral regurgitation, entered the hospital July 8, 1939, because of chills, high fever and prostration for one week following six weeks of malaise. The rectal temperature of 104.5 fell to normal on administration of sulfapyridine but rose after two days; blood culture remained positive. An hour and a half after beginning heparin he had a chill and high fever and went into collapse. He died seventeen hours later. Autopsy showed the typical lesion of acute bacterial endocarditis on the aortic valve. His reaction after administration of heparin, and the reactions in cases 6 and 7 were later traced to a faulty lot of the drug, which caused similar reactions in several patients with other conditions. Such reactions had not occurred previously and have not occurred since.

CASE 6.—R. M., a man aged 25 with well borne aortic regurgitation, which followed rheumatic fever at the age of 8 years, entered the hospital July 21, 1939, with bacterial endocarditis of one week's duration. The temperature fell to normal on sulfapyridine and blood cultures became negative. A chill and high fever occurred after one and one half hour's use of heparin of the same toxic lot as that noted in case 5 and after two further trials of the drug. He was therefore continued as a control case on sulfapyridine alone, but emboli occurred from time to time, anemia progressed, fever recurred and a blood culture, taken thirty-eight days after treatment was started, was positive. Ten days later sulfapyridine was discontinued and a new lot of heparin was begun without reaction; to date there has been little change in his condition.

CASE 7.—J. H., a man aged 41 with well compensated mitral regurgitation following rheumatic fever at 16, entered the

12a. This patient died in congestive failure Oct. 12, 1939. Autopsy revealed an area of clearcut definitely healed bacterial endocarditis with typical vegetations, fibrous and calcified, on the chronically scarred (rheumatic) mitral valve. This healed lesion is consistent in time relationship with apparently effective treatment six months earlier. The aortic valve showed also extensive rheumatic scarring, but without any vegetations of bacterial endocarditis. The myocardium is being examined for Aschoff bodies.

hospital July 20, 1939, severely ill with bacterial endocarditis of seven months' duration. The rectal temperature, which had been spiking to 103 F., fell to normal, and blood cultures became negative following the use of sulfapyridine. He received two transfusions. Heparin of the same toxic lot noted in case 5 was begun but omitted after one hour because of a chill and fever. On the eighteenth day of sulfapyridine medication, heparin of another lot was resumed without reaction; he received 185 cc. over a seven and one-half day period (a larger supply was then lacking). Sulfapyridine was continued for two weeks longer, until September 7. His improvement has been striking. He began to walk four days later (after having been bedridden for three months) and still remains free of evidence of the disease, four weeks after stopping treatment.

Sulfapyridine was continued despite nausea and vomiting, which were severe in two cases; these symptoms gradually subsided. Lymphangitis in the region of the intravenous injection in two cases cleared with change of the site of injection and hot packs.

COMMENT

We have administered sulfapyridine and heparin to six patients with subacute and one patient with acute *Streptococcus viridans* endocarditis. Two of these patients, one with subacute (patient 6) and one with acute (patient 5) endocarditis, were able to take the heparin for only an hour and a half because of reactions to a toxic lot of the drug, too short a time to expect any lasting effect on thrombus formation. Two other patients (1 and 4) were able to continue the heparin for only three days and two days respectively because of the serious course of the disease itself, which terminated fatally in a short time (two weeks or less).

The remaining three patients were able to take the heparin for more than a week, a length of time probably adequate to produce an important effect on thrombus formation. All these three patients showed striking improvement and have been free from evidences of the disease for nineteen weeks, eighteen weeks and four weeks respectively after discontinuing treatment. With these results we contrasted 246 follow-up control cases: afebrile intervals were rare for as long as five weeks once fever had set in, and no patient, so far as we could determine, remained free from signs and symptoms for that length of time except one boy, who without specific therapy did so for a full year before he died of rheumatic fever.¹³ Our three subjects, moreover, lack the characteristics of "bacteria-free" cases.¹⁴

We recognize the possible danger of excessive bleeding incident to embolism in these cases but believe it fair to accept this risk in the face of the hopeless prognosis of the disease. The chances of healing the vegetations would seem best early in the disease when they are small. In this infection, in which exacerbations with crippling and fatal embolism strike suddenly, the earliest possible diagnosis and an attempt at early therapy are important.

The treatment which we have recounted is new and still in the experimental stage; it is not to be advised except under close and careful observation and preferably in the earlier cases or less seriously ill, and there must be no doubt about the diagnosis. It can do harm, but the possible benefit may well outweigh the risks, we believe, in this almost universally fatal disease.

13. In a recent article Dr. Joseph A. Capps (Subacute Bacterial Endocarditis Due to *Streptococcus Viridans* with Special Reference to Prognosis, *Ann. Int. Med.* 13:280 [Aug.] 1939) states that he has seen no recovery from subacute bacterial endocarditis since 1924. Kelson and White.¹

14. Libman, Emanuel: A Consideration of the Prognosis in Subacute Bacterial Endocarditis, *Am. Heart J.* 1: 25 (Oct.) 1925.

Time will show how much more effective, if any, the combined sulfapyridine and heparin therapy may be than the use of either drug alone; there are likely to be infrequent recoveries from the administration of the single drug sulfapyridine or even sulfanilamide; heparin has not yet, so far as we know, been employed alone in the treatment of this disease. Neither blind to the failures nor prematurely boastful of the apparent successes, we shall continue patiently to gather further experience to learn just how good our combined therapy may prove to be and to better its technic. This preliminary report is presented because of the interesting method of attack and because that attack has in these first few months given more promise than any other method that we have ourselves used or heard of in the past.

USE OF HEPARIN IN SUBACUTE BACTERIAL ENDOCARDITIS

A PRELIMINARY REPORT

MEYER FRIEDMAN, M.D.

W. W. HAMBURGER, M.D.

AND

L. N. KATZ, M.D.

CHICAGO

Recent studies from this department¹ on experimental *Streptococcus viridans* endocarditis in dogs indicated clearly that the infection persisted because the constant deposition of platelets and fibrin on the vegetation exceeded the rate at which the vegetation implanted on the valve could be sterilized. Further studies on both dogs and human beings suffering from subacute endocarditis of the *Streptococcus viridans* variety revealed that the blood did not lack the ability to destroy the organism in vitro and that its inability to do so in vivo was due to the fact that the effective agent in the blood, the white blood cell, was unable to reach the focus of infection because of the relative avascularity of the valve leaflets and the dynamics of the blood stream flowing past the vegetations.

Because of these facts it was thought possible that the prevention of new fibrin and platelet formation by the use of an anticoagulant might allow the valvular processes of repair and sterilization to gain the ascendancy and thus terminate the infection.

With this in mind, a patient was treated with new concentrated heparin, which has been shown by Murray, Jaques, Perrett and Best² to be effective in the prevention of thrombosis in animals and possibly in man, following surgical procedures. These workers have given this heparin by continuous intravenous infusion for days to many patients with no noticeable ill effects.

The following case report deals with our observations on a single patient having subacute bacterial endocarditis, who died of cerebral hemorrhage before the treat-

From the Cardiovascular Department, Michael Reese Hospital. Read by title at the Central Society for Clinical Research, Chicago, during November 1938.

The cost of the heparin was defrayed by a grant from an anonymous benefactor. Dr. Best, Dr. Murray and their associates informed us concerning the utilization of heparin. Mr. Hutchison, of the Connaught Laboratories, cooperated in facilitating the shipments of heparin.

ment had been continued sufficiently long to evaluate the worth of the procedure:

REPORT OF CASE

History.—A. H. was admitted to the Michael Reese Hospital March 5, 1938, complaining of weakness, fever, loss of weight and loss of appetite of several months' duration. His illness began insidiously in October 1937 with a vague feeling of malaise, and as it progressed there developed a continuous fever, loss of weight and strength, and embolic accidents. Before coming to the hospital, he had been unsuccessfully treated with quinine, sulfanilamide, antistreptococcus serum and blood transfusions. The essential pathologic changes on admission were (1) evidence of weight loss, (2) anemia, (3) clubbing of the fingers, (4) a Corrigan pulse with a capillary pulse, (5) an enlarged heart with a diastolic murmur at the base and a short systolic murmur at the apex and (6) a temperature and pulse rate elevation.

Laboratory examination revealed hemoglobin 65 per cent, red blood cell count 3,150,000, white blood cell count 12,500, sedimentation time 44 mm. in an hour, Weltman reaction 5, blood sugar 88, nonprotein nitrogen 35, occasional red blood cells in the urine, normal stool, *Streptococcus viridans* in three successive blood cultures, and evidence of myocardial damage shown in an electrocardiogram.

Following a blood transfusion, the new concentrated heparin was added to physiologic solution of sodium chloride and 5 per cent dextrose solution so that each liter contained 30,000 units of heparin. A needle was fixed in the vein and, by means of a rectal drip, the solution was given continuously for ten days. The coagulation time of the blood was maintained after the second day of treatment at twenty-five to thirty minutes (five times normal for this patient).

The intravenous heparin treatment was begun on March 8 and was discontinued on the morning of March 18 because the patient at this time began to show projectile vomiting. At the same time his blood pressure began to rise and his temperature to fall, suggesting a cerebral hemorrhage. He gradually lost consciousness and in the afternoon he died. In the ten days during which he received treatment he experienced

Fig. 1.—Section of brain showing encephalomalacia and hemorrhage into ventricles.

no symptoms other than a transitory diarrhea until the final episode. No petechiae were observed during the hospital stay. No hemorrhage was noted following the withdrawal of the intravenous needles, if pressure was applied for a few seconds.

Autopsy (by Dr. Otto Saphir).—There was no evidence of internal hemorrhage in any organ other than the brain. In this organ the lateral ventricles and the third and fourth ventricles were seen to be filled with blood and there was some blood in the subarachnoid space. The source of this

hemorrhage was found to be an area of encephalomalacia (fig. 1) in the frontal lobe that had probably resulted from a previous infected embolus from seven to ten days before. The heart, particularly the left ventricle, was enlarged. The tricuspid and pulmonic valves were normal but the mitral and aortic valves showed an old healed endocarditis, and the aortic valve leaflets were seen to be the site of a vegetative process that had partially ulcerated the leaflets (fig. 2). The size of the vegetations on the leaflets were not large and were "clean"

Fig. 2.—Appearance of aortic valve showing ulcerative vegetations.

in appearance. There were two necrotic areas on the vegetations, possibly indicating dissolution of some of the fibrin. Immediately beneath the aortic valves on the wall of the left ventricle there was a minute vegetation, arising apparently by contact. There were several infarcts in the spleen in various stages of healing. The kidneys appeared normal grossly.

Microscopic sections of the brain lesion confirmed the opinion made from the gross examination. The aortic leaflet vegetations were observed to be fairly well organized, bacteria being present in the outer fringe of the thrombus, which had not yet become organized. No polymorphonuclear leukocytes in the valvular area immediately adjacent to the vegetation were observed. Small focal accumulations of round and polymorphonuclear cells were found in the myocardium. The kidneys showed an acute, disseminated glomerular nephritis.

COMMENT

We are placing this note on record in order to stimulate further clinical investigation of this method of therapy in subacute bacterial endocarditis. We are aware that there are theoretical dangers to its use, since in a disease prone to hemorrhage, as subacute bacterial endocarditis occasionally is, the use of heparin by interfering with the physiologic process of clotting may lead to intractable or even fatal hemorrhage following the rupture of a blood vessel after embolization, as might have occurred in this case. The sudden liberation of large quantities of bacteria should the vegetation disintegrate may cause an overwhelming bacteremia. The acute glomerular nephritis found in this case might have been caused conceivably by the heparin. Further, it has not been shown conclusively that heparin actually prevents the deposition of platelets and fibrin in man, although the evidence is highly suggestive. It is possible too that the promptness of instituting treatment becomes an important and vital factor. However, these contraindications to the use of heparin are not sufficient to discourage its use, since the disease itself is almost inevitably fatal and the possibility exists that some definite good may result. We therefore feel that the further trial of heparin in subacute bacterial endocarditis is warranted. Further studies are being projected in this department both on the experimental animal and on human beings.

THE BACTERIOSTATIC AND ANTITOXIC
ACTIONS OF SULFANILAMIDE

TISSUE CULTURE STUDIES

JOSEPH T. KING, M.D.

AUSTIN F. HENSCH, Ph.D.

AND

BERYL S. GREEN, M.A.

MINNEAPOLIS

The bacteriostatic theory explains the curative effects of sulfanilamide in infections in small laboratory animals as due primarily to the bacteriostatic action of the drug. As a consequence of the reduced number of organisms, there is secondary reduction in the elaboration of toxic substances (leukocidin, hemolysin and the like). The theory states that under these conditions the natural defense mechanism of the body frees the tissues of the infecting organisms.

Bliss and Long,¹ basing their conclusion chiefly on the results of experiments with mouse peritonitis caused by the Welch bacillus, reported that the only demonstrable effect of sulfanilamide on this organism was bacteriostasis. Gay and Clark,² working with rabbit empyema caused by a hemolytic streptococcus of human origin, concluded that the primary effect of the drug was bacteriostasis.

Colebrook, Buttle and O'Meara³ had earlier noted that the blood and serum of human beings and laboratory animals possessed increased bacteriostatic and bactericidal power after the administration of sulfanilamide and the prontosils. They regarded it as probable that this factor might be important in human infections but expressed surprise that the very low bactericidal power of the blood of mice should be associated with such marked curative effect.

Osgood⁴ reported early in 1938 that the major effect of sulfanilamide appeared to be toxin neutralization. However, his conclusion was promptly criticized. In an exchange of papers, Hemmens and Dack⁵ attacked the conclusion that sulfanilamide acted by toxin neutralization; while Osgood and Brownlee⁶ admitted that they were not able to demonstrate toxin neutralization with ordinary methods, they expressed the belief that conditions in tissue cultures are more comparable to conditions in the body than is true of the other in vitro tests.

The basis for criticism by Hemmens and Dack was the fact that bacteriostasis, as a factor in reducing toxin

formation, had not been properly evaluated. Osgood failed to record the size of the colonies showing smaller hemolytic zones in plates containing sulfanilamide. His data on cell suspensions could not be used to support his conclusion, since these were not in any sense quantitative.

Gross, Cooper and Lewis⁷ reported that, in the presence of serum, sulfanilamide failed to neutralize streptococcus hemolysin. Huntington⁸ reported that he was unable to neutralize hemolysin, fibrinolysin or scarlatinal toxin with sulfanilamide. Long, Bliss and Feinstone⁹ found that sulfanilamide failed to protect guinea pigs and mice inoculated with lethal doses of botulinus toxin. They noted also that high concentrations of the drug in the blood of human beings did not alter positive reactions to the Dick test. Kemp¹⁰ tested the neutralizing power of sulfanilamide for hemolysin, fibrinolysin and dermatotoxin with negative results. In discussing his observations, Kemp states: "But there is something in these observations of more importance than this disagreement [with Osgood], and that is: whatever the action of sulfanilamide, the in vitro methods fail to reveal it . . ." He was probably led to this conclusion as a result of his failure to demonstrate an antihemolytic effect of sulfanilamide on blood agar plates. It is not clear why the excellent work of English and American investigators showing beyond reasonable doubt that the drug possesses powerful antibacterial properties in vitro was not considered by Kemp. His methods are not described in sufficient detail to enable one to decide why he failed to observe an antihemolytic effect secondary to bacteriostasis. It is not stated whether he observed a bacteriostatic effect.

It is now realized that several factors may prevent any considerable bacteriostatic effect of the drug. For instance, the size of the inoculum is important, as shown by Colebrook, Buttle and O'Meara,³ who found that in the presence of very large numbers of organisms the drug was practically without effect. As Garrod¹¹ and Hoare¹² point out, this factor may account for Domagk's conclusion that there is little correlation between the in vivo and the in vitro effect of sulfanilamide.

Another factor that may have influenced Kemp's results is the type of strains used. Hoare¹² found nineteen of twenty-one strains of human origin responsive to sulfanilamide in vitro. The other two strains were from cases which did not respond to the drug. Also Bliss and Long¹³ and Bliss, Long and Feinstone¹⁴ felt that there was a significant correlation between in vivo and in vitro response. Since half of Kemp's

strains were from cases which showed good clinical response, it seems unlikely that this factor explains his results.

A further factor of importance has been emphasized by Lockwood,¹⁵ who finds that peptones interfere with the antibacterial power of sulfanilamide in vitro. Thus the composition of the culture medium must be taken into account.

Kemp's methods of measurement are not described. Hence, it is not clear whether these are sufficiently refined to detect slight differences in the size of the colony and the hemolytic zone in experimental and control sets.

As will be shown later, it is possible, when using a suitable medium and suitable quantitative methods, to demonstrate the bacteriostatic property of sulfanilamide in dilutions as high as 1:1,000,000 even when the medium contains as many as 150,000 colonies per cubic centimeter. With fewer colonies bacteriostasis is more pronounced.

Osgood¹⁶ seems reluctant to grant any importance to the bacteriostatic effect of sulfanilamide as a mechanism whereby toxin formation is reduced. This is especially difficult to understand in view of his own clear demonstration of the antibacterial power of sulfanilamide in vitro. This property of the drug is well shown in his table 2.⁴ Moreover, he noted and measured the smaller areas of hemolysis around colonies of beta streptococci grown in the presence of three different concentrations of the drug. He recorded regular and significant decreases in the diameter of the hemolytic zones. These observations he interpreted as evidence of toxin neutralization without recording the diameter of the colonies. It is obviously impossible to arrive at any conclusion as to the cause of the observed reduction in hemolysis without considering the bacteriostatic effect of the drug.

The question of decreased toxin production secondary to the decrease in the number of organisms is one of fundamental importance. This is the question raised in the criticism of Hemmens and Dack.⁵ In their reply, Osgood and Brownlee⁶ state: "The word 'neutralization' was poorly chosen and . . . we should have said 'The major action of sulfanilamide appears to be on the production of toxins or aggressins. We do not know to what this is due.'" In a later paper Osgood¹⁷ states that "sulfanilamide's major action is prevention of formation of, or neutralization of, toxins." Here it is not clear what he means by "prevention of formation." He seems to imply inhibition of toxin formation out of proportion to inhibition of bacterial growth. In the same issue, in discussing Kemp's paper,¹⁰ Osgood states: "The major action of sulfanilamide appears to be on the toxins or aggressins. We do not as yet know whether this is due to destruction of some substance necessary for the formation of these toxins or aggressins, to a direct action on the organism preventing the formation of toxins or aggressins, to the destruction of the nascent toxins or aggressins, to destruction of toxins or aggressins after they are formed, to catalysis of an antitoxin-toxin reaction or to a sufficiently slow rate of production of toxins or aggressins so that they are destroyed by the natural processes of oxidation as rapidly as they are formed."

In an effort to resolve this detailed and somewhat speculative list of possibilities into a smaller number of general propositions which can be tested experimentally, we list three obvious possibilities involved in the relation between bacteriostasis and inhibition of hemolysis (hemolysin being the only toxin considered in this paper). Decreased hemolysis in the presence of sulfanilamide might be (a) secondary to bacteriostasis caused by the drug, as demanded by the bacteriostatic theory (b) caused by neutralization of toxin, i. e., inactivation or destruction of toxin, or (c) due to "prevention of formation" of toxin, i. e., a reduction of toxin in excess of what might reasonably be regarded as secondary to the smaller number of organisms resulting from the bacteriostatic effect of the drug.

By the use of ordinary methods, it has now been established beyond reasonable doubt that sulfanilamide does not neutralize toxin. The latest paper on this phase of the problem is by Osgood and Powell.¹⁸ They confirm the results of other investigators on this point. They do not, however, discuss the bearing of their observations on Osgood's previously published opinions on toxin neutralization, or the bearing of either on the bacteriostatic theory which demands reduced toxin formation as a consequence of bacteriostasis. In discussing this paper, it was stated in *THE JOURNAL*.¹⁹

Fig. 1.—Control (a) and experimental cultures (b). Sulfanilamide 1:1,000; ninety-six hours; approximately 125 colonies per cubic centimeter; strain 2; no erythrocytes in clot. Direct photograph, $\times 1\frac{1}{4}$.

that "The results of these experiments, therefore, fail to support, although they do not disprove, the earlier experiments with cultures of human bone marrow reported by the senior author."

Evidence is offered later to show that, in tissue culture mediums composed chiefly of rabbit plasma and serum, sulfanilamide exerts a bacteriostatic effect on the three strains of beta hemolytic streptococci studied; that the effect varies directly with the concentration of the drug and inversely with the number of bacteria present; that a decrease in hemolysis is observed when bacteriostasis is observed; that the extent of the decrease of hemolysis does not suggest either toxin neutralization or "prevention of formation" of toxin beyond what might reasonably be expected as a result of the observed bacteriostasis, and that the drug inhibits the development of diffuse peripheries around colonies of beta streptococci.

MATERIALS AND METHODS

The routine tissue culture methods used have been described previously by King.²⁰ The method as applied

to the study of neoprontosil has been described by King, Henschel and Green.²¹

The Maximow technic is used, the culture being planted on a 22 mm. round cover slip. This slip is fastened to a large cover (with saline solution), which is then inverted over a deep hollow ground slide and sealed with petrolatum and afterward with a petrolatum-paraffin mixture. Cultures are incubated as lying-drop preparations at 37.5 C. in a special down-draft incubator previously described by King.²² Under these conditions there is no vapor in the dome of the chamber even in the early hours of incubation. The culture is composed of one drop of heparinized rabbit plasma and two drops of tissue extract made by extracting six day

TABLE 1.—Effect of Varying the Number of Organisms on the Bacteriostatic Effect of Sulfanilamide 1: 1,000; Twenty-Four Hours; Strain 2

Dilution of Bacterial Culture	Average Colony Diameter, Control	Average Colony Diameter, Experiment	Inhibition, per Cent
1:100,000.....	7.09	5.12	27.8
1:1,000,000.....	24.29	11.40	53.1
1:10,000,000.....	49.01	12.40	74.7

chick embryos with rabbit serum. The properties of this extract have been previously described by King and Henschel.²³

When hemolysin is to be studied, sufficient rabbit erythrocytes are introduced to make a 5 per cent suspension in the final clot. Sulfanilamide is dissolved in 0.9 per cent saline solution and sterilized by filtration. A sufficient amount of this solution is added to the tissue extract to give the required concentration in the final medium. A corresponding amount of saline solution is added to the control medium.

Organisms are added to the tissue extract after suitable dilution of the original culture in Tyrode's solution to give the required concentration in the final medium.

Fig. 2.—Control (a) and experimental (b) colonies. Sulfanilamide 1: 1,000, ninety-six hours; from 5 to 10 colonies per cubic centimeter; strain 2; no erythrocytes in clot. Slightly reduced from a photomicrograph with a magnification of 37 diameters.

The streptococci are grown in veal infusion broth. Cultures are approximately 18 hours old when used.

The three strains of beta streptococci used are all of human origin. These strains are mouse virulent. The strain BG was isolated from the cerebrospinal fluid of a patient with meningitis. The clinical response

to sulfanilamide was prompt. Strain 2 was isolated from the blood in a fatal case of septicemia. Strain 40, Lancefield group C, was isolated from a culture taken on material from the throat.

Colony diameter is used as an index of the bacteriostatic effect of the drug. The diameter of the hemolytic zone is used as an index of the hemolytic activity of the colony. The term "hemolytic index" is used to

Fig. 3.—Control (a) and experimental (b) colonies. Sulfanilamide 1: 1,000; twelve hours; strain 2; 5 per cent erythrocytes in clot. Slightly reduced from a photomicrograph with a magnification of 37 diameters.

describe the amount of hemolysis in relation to the size of the colony; i. e., the diameter of the zone of hemolysis divided by the diameter of the colony.

Measurements are made at a magnification of 60 diameters, with a standardized ocular micrometer (114 units = 1 mm.). With a mechanical stage, accurate measurements can be made of the diameter of the colony and zone of hemolysis.

Photomicrographs are made on process film. Exposure is kept down to the minimum required to register the lysed area adjacent to the colony. In this manner maximal contrast is obtained between lysed and unlysed portions of the clot. Films are developed for strong contrast. Direct photographs of cultures containing no erythrocytes are taken against a black background on process film. Panchromatic process film is used for cultures containing erythrocytes.

RESULTS

Streptococci grow rapidly in this medium, colonies usually becoming visible between the fourth and the sixth hour when the medium contains no erythrocytes. Although some strains are fibrinolytic, those used in

TABLE 2.—Bacteriostatic Effect of Sulfanilamide 1: 1,000; at Twenty-Four Hours; Strain BG; 150,000 Colonies per Cubic Centimeter

Sulfanilamide Concentration	Colony Diameter	Inhibition, per Cent
Controls.....	5.67
1:1,000.....	4.52	20.3
1:10,000.....	4.67	17.6
1:100,000.....	4.81	15.2
1:1,000,000.....	4.92	13.2

this study showed no lysis of the clot. The usual inverse relationship between the number of colonies and the size of the colonies is observed.

The time at which colonies attain maximal size depends on the number of colonies present. When the medium contains 150,000 colonies or more per cubic centimeter, growth is essentially complete in twelve hours. When the colony count per cubic centimeter is 10 or less, growth continues for at least five days.

The inhibition caused by a given concentration of sulfanilamide varies inversely with the number of colonies present. Table 1 shows the result of three dilutions of a culture of strain 2 in the medium without erythrocytes.

Figure 1 shows the effect of sulfanilamide with approximately 125 colonies per cubic centimeter and figure 2 with from 5 to 10 colonies per cubic centimeter.

With a constant number of bacterial colonies the inhibitory influence of the drug varies directly with the concentration. Table 2 shows the bacteriostatic effect on strain BG when a heavy inoculum is used.

TABLE 3.—Effect of Sulfanilamide 1:1,000 on Colony Size and Hemolysis; Strain 2

Time	Controls			Sulfanilamide			Colony Inhibition, per Cent	Inhibition of Hemolysis, per Cent
	Diameter of Colony	Diameter of Hemolytic Zone	Hemolytic Index	Diameter of Colony	Diameter of Hemolytic Zone	Hemolytic Index		
18 hrs.	39.8	65.0	1.63	12.4	32.4	2.62	68.8	50.1
24 hrs.	78.5	132.9	1.69	13.7	57.4	4.17	82.4	56.8
48 hrs.	214.7	354.0	1.64	33.7	208.1	6.20	84.3	41.2
3 days	252.4	399.5	1.58	43.2	245.7	5.69	82.9	38.5

The data in table 2 are based on measurement of between 225 and 300 colonies (in three cultures) in each concentration of sulfanilamide and control set (three cultures). With this number of colonies, strain BG shows little, if any, qualitative difference between experimental and control colonies.

In strong contrast to the very moderate inhibition shown in table 2 in the presence of a large number of colonies, this strain regularly shows more than 80 per cent inhibition with 25 colonies or less per cubic centimeter (sulfanilamide 1:1,000).

Fig. 4.—Control (a) and experimental (b) colonies. Sulfanilamide 1:1,000; forty hours; strain 2; 5 per cent erythrocytes in clot. Slightly reduced from a photomicrograph with a magnification of 37 diameters.

TOXIN NEUTRALIZATION

When 5 per cent rabbit erythrocytes are added to the medium before clotting takes place, it is possible to determine the size of the colony at the time at which hemolysis becomes evident. Subsequent measurements of the diameter of the colony and of the zone of hemolysis make possible a correlation between these two factors.

Early observations and measurements show that, when a colony attains a given size, hemolysis commences whether sulfanilamide is present or not. Hemolysis starts when the colony attains a size of approximately 10 units.

Figure 3 shows a twelve hour control and experimental colonies of approximately the same size. There is no evidence that a high concentration (100 mg. per hundred cubic centimeters) of sulfanilamide has reduced the hemolytic activity of the colony. As is evident from tables 3 and 4, there is a lag in the development of experimental colonies due to the bacteriostatic effect of the drug. This results in less hemolysis in

Fig. 5.—Control (a) and experimental (b) cultures. Sulfanilamide 1:1,000; twenty-four hours; strain 2; 5 per cent erythrocytes in clot. Direct photograph, $\times 1\frac{1}{2}$.

experimental cultures at a given time. However, when experimental colonies are compared with control colonies of the same size, there is no evidence of hemolysin neutralization.

Study of the subsequent development of the cultures likewise fails to reveal any evidence of neutralization of preformed hemolysin. Figure 4 shows well developed colonies from experimental and control sets (forty hours).

Figure 5 is made from direct photographs of experimental and control cultures of strain 2 (sulfanilamide 1:1,000). In this figure the lysed areas are dark while the unlysed portion of the clot is light.

Detailed observations on two experiments with strain 2 are shown in tables 3 and 4. In the experiment shown in table 3 the control colonies showed the usual diffuse peripheries. In the other experiment (table 4) the control colonies grew as compact masses.

In both experiments typical inhibition of both colony and hemolytic zone is shown.

TABLE 4.—Effect of Sulfanilamide 1:1,000 on Colony Size and Hemolysis; Strain 2

Time	Controls			Sulfanilamide			Colony Inhibition, per Cent	Inhibition of Hemolysis, per Cent
	Diameter of Colony	Diameter of Hemolytic Zone	Hemolytic Index	Diameter of Colony	Diameter of Hemolytic Zone	Hemolytic Index		
9 hrs.	10	5	50.0

2½ days	81	352	4.35	60	300	5.00	25.9	14.8

In all cases it has been noted that the hemolytic index rises to a maximum and then declines somewhat. The experimental cultures reach the maximum later than the controls.

The hemolytic index is higher in the cultures containing sulfanilamide than in the controls. As will be noted later, the significance of this fact is not entirely clear at present.

BACTERICIDAL PROPERTIES OF SULFANILAMIDE

In this medium there has been no consistent reduction in the number of colonies in experimental cultures.

QUALITATIVE CHANGES CAUSED BY SULFANILAMIDE

With large inoculums no characteristic change is noted. Sometimes experimental colonies appear less dense. When the inoculum is sufficiently small to permit colonies to attain any considerable size, the drug causes qualitative change in those strains which show diffuse peripheries. The drug regularly inhibits the development of such peripheries. The resulting colonies are small and compact. The strains studied have not shown a characteristic qualitative response to the drug when they failed to develop diffuse peripheries.

It has been noted that colonies whose diffuse peripheries have been inhibited by sulfanilamide frequently show heavy chains invading the clot. The amount of chain formation is quite variable. In our experience, from three to twelve chains can be regarded as typical. When chains are present they are not evenly distributed around the colony but are grouped in a loose net in a rather limited area.

Rarely a colony may develop a complete periphery composed of this typical loose network of heavy chains. We have seen only a few such colonies and those developed rather late.

We wish especially to emphasize the difference between this type of periphery and the normal, diffuse periphery seen around control colonies. In the latter the organisms are widely scattered, singly and in groups of two or three. In the presence of sulfanilamide, however, the normal mechanism of division is so modified as to produce long chains.

Gay and Clark² had observed earlier that when streptococci were grown in serum containing sulfanilamide the organisms grew in long chains of pleomorphic and metachromatic forms. Later, Meyer²⁴ described "great masses of markedly deformed, swollen streptococci, growing in endless chains," in relation to the "clumping reaction," which he observed in serum broth cultures of streptococci containing a sulfanilamide-sugar compound.

Lockwood¹⁵ described long chains of abnormal streptococci growing in mediums containing sulfanilamide. This tendency to form long chains in the presence of the drug was also noted by Chandler and Janeway.²⁵

COMMENT

Of the many factors having a probable bearing on the mechanism of action of sulfanilamide, we are concerned in this paper with the following: (1) the bacteriostatic action in vitro as influenced by the concentration of the drug and the size of the inoculum; (2) the correlation between the bacteriostatic effect and the amount of hemolysis; (3) the qualitative changes caused by the drug.

It is now realized that certain experimental conditions are required to demonstrate the effects of sulfanilamide in vitro, and all failures to demonstrate such effects when therapeutically responsive strains of beta streptococci are used must be examined in the light of this knowledge.

Colebrook, Buttle and O'Meara³ reported that the drug was almost without effect in the presence of very large numbers of organisms. Lockwood¹⁵ also found a

greater effect when using a smaller inoculum. Recently, Chandler and Janeway²⁵ reported the same experience. These investigators worked with fluid mediums.

In tissue culture clots we have found the bacteriostatic effect of the drug to vary inversely with the number of colonies present (table 1). That it is possible, however, to demonstrate moderate bacteriostasis in this medium, even in the presence of relatively large numbers of organisms, is shown in table 2.

Lockwood¹⁵ found that peptones interfere with the action of sulfanilamide and pointed out the importance of avoiding the use of mediums containing such substances if one wished to obtain the full effect of the drug.

Lockwood, Coburn and Stokinger²⁶ reported, on the basis of clinical experience, that "the presence of debris, human or bacterial, diminished the effectiveness of sulfanilamide on the hemolytic streptococcus. In each instance the organisms remaining in broken down tissue maintained their virulence. It is not known whether the debris itself had a protective action on the organisms or whether there was insufficient penetration of the drug into the locus."

We²⁷ have found that the presence of a small fragment of tissue in a tissue culture greatly antagonizes the effects of sulfanilamide even at a considerable distance from the fragment. We have observed this effect with concentrations of sulfanilamide as high as 140 mg. per hundred cubic centimeters. We believe that the products of tissue disintegration exercise a protective effect on the organisms.

Since the extracts used in making the clots of tissue culture were made by shaking six day chick embryos in serum, the question might be raised whether enough peptone-like substance would be extracted to cause a "peptone effect"; i. e., a reduction in the effect of sulfanilamide.

It was pointed out by Colebrook, Buttle and O'Meara³ that the effect of sulfanilamide was much less marked in the blood of the small laboratory animals than in human blood. Except for very small inoculums, they found the drug to be bacteriostatic but not bactericidal in the blood of these animals. Gay and Clark² observed only bacteriostasis in rabbit serum containing the drug. In neither of these cases was there any addition of peptone-like substance. In view of these facts and of the further fact, already noted, that the drug is much more effective in the cell-free medium than in the medium containing a small tissue fragment, we assume tentatively that the medium reacts as though free of any significant amount of peptone-like material.

As pointed out earlier, Bliss and Long¹³ and Bliss, Long and Feinstone¹¹ obtained satisfactory correlation between in vivo and in vitro response, and Hoare¹² found 100 per cent correlation in a study of twenty-one strains.

In the present study we have used only Lancefield group A and C strains. The strains reported, and others less intensively studied, proved responsive to the drug in the tissue culture medium.

It now seems safe to assume that all therapeutically responsive strains of beta hemolytic streptococci are inhibited by sulfanilamide in vitro if the experimental conditions are suitable.

27. King, J. T., and Henschel, A. F., to be published.

In view of the well known ability of the streptococcus to produce destructive toxins, it is natural that considerable interest has attached to the possibility that sulfanilamide might either reduce the amount of toxin formed or neutralize toxin. The bacteriostatic theory assumes that there is a reduction in the amount of toxin formed secondary to the reduction in the number of organisms brought about by the drug. In the tissue culture medium we have always found that when the drug causes a decrease in the size of the colony it also causes a decrease in the size of the hemolytic zone. Typical results are shown in tables 3 and 4.

We have observed that hemolysis starts when the colony reaches a certain size whether or not sulfanilamide is present. There is a lag in the development of experimental colonies as compared with the controls. Otherwise the sequence of events is fundamentally alike in the two. Study of the subsequent development of the colony shows that the drug continues to exert a bacteriostatic effect and that the amount of hemolysis is less in experimental cultures. On the basis of colony size, however, colonies growing in 100 mg. per hundred cubic centimeters of the drug produce a larger rather than a smaller zone of hemolysis; i. e., they show a higher hemolytic index. Possible explanations for the higher hemolytic index observed in experimental cultures will be considered after the qualitative changes caused by the drug have been discussed.

It is clear that if the drug neutralized hemolysin or reduced the formation of hemolysin out of proportion to the reduction in the number of organisms, the hemolytic index of experimental colonies would be lower. This is not the case, however. Consequently, we can only conclude that such reduction in hemolysis as is observed is secondary to the bacteriostatic effect of the drug.

Most of the strains available to us grow with diffuse peripheries in this medium, provided the inoculum is not too large. Some strains, for example strain 2, are not constant in this regard, at times showing peripheries and at other times growing as compact colonies.

We have never seen a normal diffuse periphery in a culture containing sulfanilamide unless the effects of the drug were antagonized by the presence of tissue.²⁷ The drug inhibits the rapid invasion of the clot usually seen around control colonies.

As already noted, an inhibited colony may show a variable number of long, heavy chains projecting from some point on the periphery or, rarely, a complete periphery composed of a loose network of such chains.

In considering possible explanations for the higher hemolytic index observed for colonies growing in cultures containing sulfanilamide, the qualitative change in colony form usually caused by the drug must be taken into account. It has been pointed out that the drug inhibits the development of the wide, diffuse periphery usually seen around colonies of beta streptococci in this medium. As may be seen by comparing the control colonies shown in tables 3 and 4, this diffuse periphery is not as active in producing hemolysis as the more dense central part of the colony. In the experiment detailed in table 3, strain 2 grew with the usual peripheries. The hemolytic index reached a maximum of 1.69. An experiment with the same strain is shown in table 4, in which the colonies are of the compact type showing a maximum hemolytic index of 4.72. From these facts it is evident that a more compact colony has a higher hemolytic index.

It is possible that the higher hemolytic index observed in cultures containing sulfanilamide is due to the formation of a more compact colony. It is clear that this factor is important when the controls grow with the usual diffuse peripheries, as in the experiment shown in table 3. The interpretation is complicated however by the fact that, even when the control colonies fail to develop diffuse peripheries, sulfanilamide causes a higher hemolytic index. In this case it is not evident that the drug causes the development of more compact colonies, but the possibility cannot be ruled out.

We have considered the possibility that erythrocytes might be more vulnerable to lysis by streptococcus hemolysin in the presence of sulfanilamide. There is, however, no experimental evidence to support this theoretical possibility.

Another possible explanation is based on the fact that sulfanilamide is known to form numerous conjugation products. Czarnetsky and his associates²⁸ have found that certain derivatives of the streptococcus will conjugate with the drug to form hemolytic products. It is therefore possible that the drug combines with some product of bacterial metabolism to form a hemolytic agent. Should this ultimately prove to be true, it is interesting to speculate what bearing it might have on the cause of the severe anemias now known to occur occasionally during administration of the drug.

SUMMARY

A tissue culture study has been made of the bacteriostatic and antihemolytic properties of sulfanilamide.

All strains of beta streptococci studied were inhibited.

The bacteriostatic effect varied directly with the concentration of the drug and inversely with the number of bacterial colonies.

Reduction in hemolysis was observed to accompany bacteriostasis.

Correlation of the reduction in hemolysis with the observed bacteriostasis leads to the conclusion that the antihemolytic effect is secondary to bacteriostasis.

The drug regularly inhibits the wide, diffuse peripheries usually seen around colonies of beta streptococci growing in clots of tissue culture.

The drug causes the development of abnormal, long chains of streptococci.

CONCLUSIONS

Sulfanilamide is bacteriostatic for the strains of beta streptococci studied. The effect varies directly with the concentration of the drug and inversely with the number of bacteria.

The antihemolytic effect is secondary to the bacteriostatic effect. There is no evidence that the drug neutralizes hemolysin or reduces its formation beyond what can be accounted for on the basis of the reduced number of organisms involved.

The drug modifies the normal mode of division and reduces the ability of the organisms to invade the clot.

Life History of the Housefly.—The housefly passes through a complex metamorphosis, i. e. egg, larva (maggot), pupa and adult or fully winged insect. Under warm summer temperatures the egg stage requires about twenty hours, the larval stage about five days, the pupa about four days, a total of about ten days from egg to adult insect. This allows for the development of from ten to twelve generations in one summer.—Hermes, William B.: *Medical Entomology*, New York, Macmillan Company, 1939.

EXPERIMENTAL CHEMOTHERAPY WITH
SULFANILAMIDE AND RELATED
COMPOUNDS

SANFORD M. ROSENTHAL, M.D.

Senior Pharmacologist, Division of Pharmacology, National Institute
of Health, United States Public Health Service

WASHINGTON, D. C.

Bacterial chemotherapy has emerged from the laboratory. It is primarily in the laboratory that progress must be made in the development of more effective compounds and of compounds active against diseases as yet not influenced by chemical treatment. It is also in the laboratory that a better understanding of the mode of action of these drugs and of their toxic effects can be obtained.

I wish to discuss some aspects of the problem from a laboratory point of view. This new field has been characterized by too hasty clinical application of experimental results. Some shortcomings in our knowledge and some of the difficulties encountered in transferring results from one species to another will be brought out. This paper is not intended to be a comprehensive review of the field of bacterial chemotherapy but a discussion of certain phases of the subject with which I have had experience in the laboratory.

PHARMACOLOGIC CONSIDERATIONS

The acute toxicity of sulfanilamide for several species of higher animals has been adequately established. Given in single doses by mouth, it is tolerated in amounts of from 1.5 to 3 Gm. per kilogram, depending on the species. The work of Marshall¹ and his colleagues has added much to an understanding of the acute toxicity, absorption, distribution in the body and excretion of sulfanilamide. It must be pointed out that these toxicity values were established on normal animals. My associates and I have observed that in mice rendered extremely ill by infection and toxins, such as is seen following the injection of large numbers of meningococci of low virulence to mice, deaths were often encountered following one third of the maximum dose normally tolerated.

Of more importance to the clinician is the question of chronic toxicity, and in this our knowledge is inadequate. Marshall, Emerson and Cutting² found sulfanilamide well tolerated over a period of weeks by the rat and dog. Molitor and Robinson³ have quite recently studied the acute and chronic toxicity of sulfanilamide and benzysulfanilamide in mice, rats, dogs and rabbits. With large doses of sulfanilamide cumulative toxicity and pathologic changes were manifest. Their chronic toxicity studies on rabbits were unsatisfactory. Contrary to prevalent opinion, water increased the toxicity of sulfanilamide in their experience. We⁴ have found that in the rabbit under certain dietary restrictions from 0.5 to 1 Gm. per kilogram for two weeks produced toxic symptoms and frequent deaths.

4. Rosenthal, S. M.: Studies in Chemotherapy: VIII. Some Toxic Effects of Sulfanilamide and Sulfanilyl Sulfonamide to Rabbits and Chickens, *Publ. Health Rep.* **54**: 22 (Jan. 1939).

Chickens on this dosage showed emaciation, motor weakness and a high mortality. Halpern and Mayer⁵ and Rich⁶ have also noted cumulative toxic effects in the guinea pig. Still another illustration of species variation in toxicity is seen in that frequent toxic manifestations observed in human beings such as fever, dermatitis and hematologic changes are encountered rarely or not at all in experimental animals. However, cyanosis has recently been produced in rats and chickens, and susceptible species may be found in which the other toxic effects seen in man may be produced.

In dealing with compounds of low water solubility this discrepancy between acute and chronic toxicity may be even more marked. Thus with sulfanilyl sulfanilamide the enormous single doses tolerated by animals give a misleading indication of the results obtained on repeated administration. It must therefore be concluded that the acute toxicity of this group of drugs is no reliable criterion of the effects to be obtained on their repeated administration and that considerable variation in toxic manifestations may be encountered from one species to another.

THERAPEUTIC RESULTS IN ANIMALS

There is a definite need for some standardization of the experimental assay of chemotherapeutic activity of these new drugs. Widely divergent results have been obtained in different laboratories. Apart from such factors as toxicity and the rate of absorption and excretion, therapeutic effectiveness is influenced by the dosage, the route of administration, the onset and duration of therapy, the period of observation following therapy, the strain of organism, the infecting dose and virulence of the organisms, the species and number of the animals and the condition of the animals employed.

While there is universal agreement on the activity of sulfanilamide in experimental beta hemolytic streptococcus infections, the dosage required to bring about the survival of the majority of infected mice varies from one third to one tenth of the maximum tolerated dose. At best this is not an impressive therapeutic index and emphasizes from the laboratory point of view the necessity for large doses to bring about good therapeutic results.

On pneumococcal infections in mice sulfanilamide has a less marked action, bringing about chiefly a prolongation of life.⁷ That this degree of activity cannot be accepted as valid for man is shown by the fact that sulfanilamide has a much better action in pneumococcal infections in rabbits, and in rats a high percentage of cures can be effected.⁸

The increased effectiveness of sulfapyridine against pneumococcal infections was first demonstrated by Whitby.⁹ While preliminary experiments have not

confirmed the uniformly high curative effects of this compound reported by him in mouse infections, results have shown a definite superiority over sulfanilamide.

The effectiveness of sulfanilamide in experimental meningococcal infections, demonstrated first by Buttle, Gray and Stephenson,¹⁰ has been amply confirmed. It should be noted that the two infections most susceptible to therapy in the laboratory, streptococcal and meningococcal, have given the most encouraging results in the clinic.

On staphylococcal infections in mice sulfanilamide has only a slight activity, but more favorable effects have been obtained with sulfanilyl sulfanilamide,¹¹ and recently with sulfapyridine.¹²

Space will permit only brief mention of the positive laboratory results in other infections. Following the successful clinical use in gonorrhea, Levaditi¹³ first demonstrated marked curative action of sulfanilamide and some related compounds in gonococcal "toxi-

Chart 1.—Eight daily doses of 1 Gm. per kilogram of sulfanilamide to chickens caused progressive loss of weight, weakness, particularly marked in the legs, and delayed death.

infection" in mice. Levaditi¹⁴ had also demonstrated for several bacterial endotoxins a true antitoxic action for some sulfur compounds, although no effect could be shown against bacterial exotoxins.

Favorable laboratory results have been reported in infection with *Clostridium welchii*,¹⁵ *Escherichia coli*,¹⁶ brucellosis,¹⁷ *Bacillus aertryke*, *B. typhosus*¹⁸ and *B. pestis*.¹⁹ An inhibitory but not curative effect has been found in experimental tuberculosis in guinea pigs.⁶

EXPERIMENTAL CHEMOTHERAPY—ROSENTHAL

1712

COMBINED DRUG AND SERUM THERAPY

Although the opportunities previous to the discovery of prontosil for studying the relationship between drug therapy and therapy with specific serum have not been numerous, two earlier examples of a synergistic effect have been demonstrated in the laboratory. Moore²⁶ employed ethylhydrocuprine plus antiserum in pneumococcic infections in mice. In both instances a higher curative effect was obtained with combination therapy than with the use of drug or serum alone.

In our limited investigations, the results with the use of a combination of sulfanilamide and streptococcic infections in mice demonstrated in each instance a synergistic effect. The curative action was greater than the additive effects of the two agents used separately. Similar results for pneumococcic infections in mice were reported by Gross and Cooper,⁸ for streptococcic infections by Brown.³² Osgood,³³ and for meningococcic infections by Brown.³² Osgood,³³ working with in vitro cultures of bone marrow, has also reported augmented effects on pneumococci when both drug and specific antiserum were present. These results are in harmony with the concept that the drug acts directly on the organisms, in some way

infections it is difficult to bring about sterilization of the animal by brief periods of therapy, and under these circumstances a high percentage of relapses and late deaths occur. In the presence of severe infections this would emphasize the need for continued drug therapy, so that the defense forces of the body may be given

Chart 5.—The synergistic action of sulfanilamide and serum (antibacterial) therapy in experimental streptococcic septicemia in mice; ten mice to each group; dosage of serum and drug adjusted so that either alone had little curative action; combination therapy yielded a high percentage of cures; treatment given at times indicated by arrows; streptococcus originally isolated from a case of scarlet fever; similar results obtained with streptococci isolated from erysipelas and from general sepsis.

Chart 4.—The action of sulfanilamide in pneumococcic infections in rats. One cc. of broth culture of Mulford type I pneumococcus, diluted 1:10; type II, 1:10; type III, 1:10; intraperitoneally. Drug given subcutaneously as indicated at arrows.

damaging or inhibiting them, so that the final eradication of the infection can be brought about by the natural defense mechanisms of the body.³⁴ In experimental

adequate opportunity to mobilize; when such forces are inadequate, experimental observations suggest the favorable effects of employing specific serum therapy, when such is available, in addition to drug therapy. While preliminary clinical use of combination therapy is suggestive, particularly in such conditions of high mortality as pneumococcic meningitis,³⁵ further laboratory and clinical experience is needed to evaluate this procedure.

THE RELATION OF CHEMICAL STRUCTURE TO CHEMOTHERAPEUTIC ACTION

Since the discovery of prontosil, an impressive number of compounds have been investigated for antibacterial action. Of the numerous derivatives of sulfanilamide few possess greater activity than the parent compound against streptococci, but sulfapyridine is an illustration that derivatives can be obtained with enhanced activity against specific infections. The discovery by Buttle³⁶ and Fournau³⁷ that 4,4'-diaminodiphenylsulfone and certain derivatives were many times as active against streptococci as sulfanilamide marked an important advance, since these compounds contain no sulfonamide group. The active radical common to this entire class of compounds may be characterized as

Levaditi³⁹ has reported activity for dihydroxy diphenylsulfone, demonstrating that nitrogen is not in all cases necessary for activity.

That sulfur is not essential for activity has been shown by Rosenthal and Bauer⁴⁰ in that asymmetrical arsenic derivatives analogous to the sulfones

possess antistreptococcal action. We⁴⁰ also found simultaneously with Mayer and Oechsli⁴¹ that *p*-nitrobenzoic acid

has a slight action against pneumococcal and streptococcal infections in mice. These brief examples serve to illustrate the wide chemical front along which the conquest of bacterial infections may be approached.

A survey of the numerous derivatives brings out the importance of an amino or nitro group in the para position in the benzene ring. Substitutions in the amino group of sulfanilamide are much more prone to diminish antibacterial activity than substitution in the sulfonamide group. Mayer⁴² has found that an intermediate oxidation product of the amino group, the hydroxylamine (NHOH) derivative of sulfanilamide, is highly active in the test tube against streptococci. Mayer has postulated the slow formation in the body of this derivative as the basis for activity of sulfanilamide. The hydroxylamine derivative as such (*p*-hydroxylamino-benzene sulfonamide) is unstable when injected into the body; the feeble therapeutic activity shown when this compound itself is employed is believed by Mayer to be due to its rapid breakdown. Mellon and

Following the administration of sulfanilamide, not all of the compound can be recovered as the free or acetylated derivative.¹ It is thus of importance to know more of the fate of that portion of the drug which is unaccounted for.

Chart 7.—The increased effectiveness of combined drug and serum therapy in type I pneumococcal infection in mice. Treatment subcutaneously begun five and one half hours after inoculation. Units of serum (Felton) and dosage of sulfanilamide are indicated by arrows on the chart.

We⁴⁴ have recently devised tests for the estimation of aromatic hydroxylamines and for further oxidation products of aromatic amino groups, that can be carried

Presence in Urine of an Hydroxylamine Derivative of Sulfanilamide Following Oral Administration of 1.5 Gm. of Sulfanilamide in 100 Cc. of Water to Two Rabbits of 2.8 and 2.65 Kg. Weight

	Urine Volume	Free Sulfanilamide	Total Sulfanilamide	Hydroxylamine Sulfanilamide
2 hrs.....	30 cc.	30 mg.	60 mg.	0.45 mg.
4 hrs.....	93 cc.	93 mg.	177 mg.	2.14 mg.
6 hrs.....	25 cc.	87 mg.	168 mg.	2.4 mg.

out in the presence of sulfanilamide or other aromatic amino compounds. Following the administration of sulfanilamide to rabbits, it has been possible to demonstrate from 1.5 to 5 per cent of the free sulfanilamide in the urine present as a compound giving the reactions characteristic of the hydroxylamine derivative (shown in the accompanying table).⁴⁵ This of course does not finally prove that the hydroxylamine derivative is the active agent, but it should now be possible to correlate the presence of this compound with bacteriostatic effects and to investigate further the relation of hydroxylamine derivatives and of further oxidation products of the amino group to toxicity and to therapeutic activity.

SUMMARY

The acute toxicity of sulfanilamide and related compounds is no reliable index of the toxicity to be encountered on continued administration, particularly under adverse conditions of infection or dietary restriction. Variations in the toxic manifestations of sulf-

Chart 6.—Three experiments with meningococcal infections showing the marked curative effects of combined drug and serum therapy when each alone yielded poor results; treatment subcutaneously two hours after infection with 0.8 Gm. per kilogram of sulfanilamide and 0.5 cc. of 1:5 dilution of meningococcal serum.

his co-workers⁴³ have also suggested that the hydroxylamine derivative may be the active agent by virtue of its anticalase activity.

45. Similar reactions have also been obtained in the urine of dogs, of rats and of man following sulfanilamide administration.

anilamide occur in different species of animals. There is inadequate knowledge of the chronic toxic effects on laboratory animals.

Relatively large doses of sulfanilamide and repeated therapy are required to bring about a high percentage of cures in streptococcal infections in mice.

With pneumococcal infections, marked variation in response to therapy occurs with different species of animals.

Combination of sulfanilamide therapy with specific antiserum in pneumococcal, meningococcal and streptococcal infections in mice brings about more favorable results than those obtained with either type of therapy used alone.

It has been shown that sulfur is not essential to therapeutic activity. Antibacterial properties have been demonstrated for some aromatic arsenic compounds, as well as for *p*-nitro benzoic acid.

Following the oral administration of sulfanilamide to rabbits, a small percentage of an oxidation product of the amino group (hydroxylamine) has been detected in the urine. Other investigations have suggested the possible significance of this derivative in the mechanism of action of sulfanilamide.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. KING ET AL. AND DR. ROSENTHAL

DR. CHARLES L. FOX JR., Boston: The paper of Dr. King and his co-workers is interesting but I would make one observation to be considered in evaluating some of his facts. Hourly bacterial counts of cultures with sulfanilamide (10 mg. per hundred cubic centimeters) and controls without sulfanilamide show these three features: For the first three hours growth is equal in the two. Then the control proceeds along the logarithmic phase of growth whereas the sulfanilamide culture grows but slightly until the eighth or ninth hour. Then this period of bacteriostasis (from the third to the ninth hour) ends and the sulfanilamide culture grows out equaling the control. If, therefore, one has not observed the culture between about three hours and about eight hours, one is likely not to see any bacteriostatic effect whatever. In table 5 which Dr. King showed, and in all his observations, I believe the first observation of the colony was at nine hours. His other observations were at about twelve hours. If one considers this fact, one will recognize that the major effect of the drug occurs between about the third and the ninth hour, but after nine hours one is not going to see so much effect. It may be possible to recognize that a culture the growth of which has been held up for three or four hours here at this time, at about seven or eight hours, is a younger and possibly a more actively growing culture than the control which has been growing vigorously during that period. There may be a possibility that this increased hemolytic effect of the organism grown in sulfanilamide is due to the fact that his observations, beginning at about nine hours, are on cultures with controls which are not growing as actively at this stage as the sulfanilamide cultures. In evaluating all sulfanilamide studies, I think it must be realized that the major effect of the drug occurs between about the third and the ninth hour.

DR. SANFORD M. ROSENTHAL, Washington, D. C.: I think we are all on the right track in mechanism, but I just want to add that most of our work has been in the test tube and that all mechanisms of action based on *in vitro* experiments remain theories until they are demonstrable in the living organism. I feel that we now have to take our test tube work over into the animals to see whether the same thing applies. I should like to ask Dr. Shinn whether he has studied the blood of animals or human beings under sulfanilamide for the catalase activity or for peroxide content.

DR. JOSEPH T. KING, Minneapolis: The question was raised by Dr. Fox whether with this method one might overlook an important phase of the bacteriostatic action of sulfanilamide

during the early part of the incubation period. Since the diameter of the colony is used as the index of growth rate in this medium, no information exists concerning growth until the colonies can be measured microscopically. In the medium without erythrocytes the colonies usually appear between the fourth and the sixth hour of incubation. On the basis of colony diameter the maximal bacteriostatic effect of the drug occurs at a point in time later than that at which colonies become measurable in both experimental and control cultures. Dr. Fox also pointed out that, although the growth curve of cultures containing sulfanilamide is usually greatly retarded in the early part of the incubation period, it may eventually rise above the control and he raised the question whether this might account for the higher hemolytic index observed in our cultures. With my technic I usually observe a decrease in the bacteriostatic action of the drug following the maximum, which usually occurs somewhere near the twenty-four hour period. This tendency is probably more pronounced when the cultures contain erythrocytes. I have never observed the bacteriostatic action to fail completely—the experimental colonies never become larger than the controls in this medium. This fundamental difference between fluid mediums and tissue culture clots where the organisms grow as colonies must be kept in mind when interpreting results. In any event this suggestion could hardly account for the fact that a higher hemolytic index is found in cultures containing sulfanilamide, since this term expresses the hemolyzing power of a colony in relation to its size, i. e. the diameter of the hemolytic zone divided by the diameter of the colony. The absolute amount of hemolysis is less in experimental cultures than in controls. The experimental colonies produce wide zones of hemolysis in relation to their size.

L. E. SHINN, PH.D., Pittsburgh: With regard to the paper of Dr. Rosenthal, I am glad to see some one embark on a study of compounds other than the interminable ringing of changes on the amino attached to the sulfur. So far as I know, no one has made any systematic efforts to get at the real fundamentals of the structure, replacing the sulfur with other substances and making the changes in the heart of the molecule, so to speak. We have begun work similar to that which he has discussed with regard to the benzoic acid. I am preparing to do some work on arsenicals in the belief that that group, the group which is now the sulfonamide group, is not in itself particularly important or critical. From my point of view, the action of that group probably lies in its influence on the amino group. Its effect is indirect, unstabilizing the amino group to just the right degree. Dr. Rosenthal asked whether I had examined the tissue fluids of animals or human beings with regard to the anticalase mechanism, production of hydroxylamine, and so on. I must say that I have not. I had considered it hopeless to hunt for the hydroxylamine derivative *in vivo*. The question was raised as to what is going to be done with some other organisms—the staphylococcus, the diphtheria bacillus, *B. coli* and the gonococcus. On that question I cannot say very much. I feel that we are going to find in those organisms factors which will allow the application of this or a very similar theory in explanation of mechanism. For example, the gonococcus is presumed to be a producer of an appreciable amount of catalase and, since it is a producer of catalase, one must presume that that catalase serves some purpose. The indication would be that the organism is extremely susceptible to hydrogen peroxide and therefore that interference with catalase may be even more effective.

DR. I. S. RAVDIN, Philadelphia: The workers who believe that anticalase activity is responsible for the mode of action of sulfanilamide must explain why this drug is effective against the colon bacillus, which grows well in the presence of hydrogen peroxide. The explanations advanced this morning must not be accepted as proofs of the mode of action of these very interesting and useful substances but further work must be awaited.

DR. FOX: Dr. Rosenthal said he would like further evidence as to the presence in the blood of patients or animals of some of these compounds which assumedly are formed from sulfanilamide *in vivo*. That evidence has been difficult to get.

We have taken specimens of blood of sulfanilamide treated patients and, by using the recording spectrophotometer at the Massachusetts Institute of Technology, have been able to get a smooth line curve of the transmission spectrum of the blood of these patients. Such blood almost always contains methemoglobin, as many others have shown, and sometimes sulfhemoglobin, but, in addition, in the red end of the spectrum, where hemoglobin absorbs but slightly, there is a residual absorption. The human eye is but slightly sensitive, and the ordinary spectrophotometer is less accurate in the region above 650 millimicrons. With the recording spectrophotometer we have gone from 400 to 700 millimicrons. From about 650 to 700 millimicrons there is definite absorption strikingly similar to the absorption by the products of the ultraviolet irradiation of sulfanilamide. Important additional evidence for the presence of these oxidation products in patients' blood is that, added *in vitro*, these products convert hemoglobin to methemoglobin. Sulfanilamide itself has absolutely no such effect. Dr. Rosenthal said that the compound nitrosobenzene, the oxidized form, is bacteriostatic. I have found that addition of a paradimethylamine group produced a compound 100 times more bacteriostatic than nitrosobenzene. These substances are reversible oxidizing systems and *in vitro*, in mice, produce fatal methemoglobinemia so that therapeutic tests were unsuccessful.

SEROLOGIC DISCREPANCIES IN SYPHILIS

THE POSITIVE HINTON-NEGATIVE WASSERMANN PROBLEM

G. MARSHALL CRAWFORD, M.D.

AND

LEON F. RAY, M.D.

PORTLAND, ORE.

The occurrence of a positive Hinton with a negative Wassermann reaction in patients with late syphilis gives rise to delicate problems of diagnosis as well as to the question of activity in old cases and the advisability of further treatment. The first technic of the Hinton test¹ was adopted for routine use at the Massachusetts General Hospital in 1929. The present method,² which is comparable to the Eagle, Kahn, Kline and Kolmer tests as to specificity and surpasses them in sensitivity,³ is similar in principle to the Eagle, Kahn and Kline tests. When the Hinton test was first used at the Massachusetts General Hospital it was applied to all bloods in conjunction with the Wassermann test. The technic of the latter test is a modification of the standard Wassermann test.⁴ A general agreement between the two tests led to the practice of omitting the Wassermann test unless the Hinton test was positive. When an additional check was desired, a portion of the specimen was sent to the Massachusetts State Board of Health Laboratory, where the Hinton technic is under the supervision of its originator. With the pas-

sage of time, however, cases exhibiting a disagreement between the two tests gradually accumulated.

In new infections, the development of increased sensitivity in tests for syphilis facilitated diagnosis. In late syphilis, however, more delicate tests increased the importance of demonstrating clinical evidence of the disease. The specificity of blood serologic reports might otherwise be open to question. The results of nationwide serologic conferences for evaluation by the United States Public Health Service indicate that these highly sensitive technics are accurate. The extensive application of such methods of blood examination has given rise to many intricate and perplexing problems. Some doubts arose when new technics produced a positive reaction accompanied by a simultaneous negative report with an older standard test. In early syphilis "serologic cures" were delayed, with a corresponding increase in serofast cases. In late syphilis, especially the asymptomatic group, still more difficulties appeared. It was questioned whether persistently positive serologic examinations by such delicate technics meant continued activity of the disease. Criteria of adequate therapy were consequently open to further consideration. Many old Wassermann-negative cases exhibited positive reactions to the new tests. Likewise, numerous unsuspected cases appeared which were negative by older methods. Some clinicians doubted that a positive report by such sensitive procedures meant syphilis in the face of a negative Wassermann reaction unless other evidence was provided. Cannon⁵ stated that a properly controlled "4 plus" Wassermann reaction meant active syphilis in need of treatment, with certain exceptions including yaws and leprosy. Can his statement be applied as well to the more sensitive tests? Kolmer⁶ expressed the opinion that serologic positivity in an apparently healthy person, even with previous adequate therapy, indicated the persistence of syphilitic infection. He further stated that serologic relapse meant renewed activity of foci of the disease. Kolmer also indicated that therapy was needed to aid immunity and prevent progression of the disease. Can such beliefs be applied to cases exhibiting a positive serologic reaction by sensitive methods when the Wassermann reaction is negative? The questions are partially answered by the ratings of accuracy attained by many of the sensitive tests in the reports of serologic congresses. We have attempted to clarify some of these problems from the clinical aspect by the following work.

DATA

In the period from July 1936 to July 1938 there were 2,862 new admissions to the syphilis clinic at the Massachusetts General Hospital. Excluding early syphilis, there were 335 cases (11.7 per cent of the total) which were found to have a positive Hinton and a negative Wassermann reaction on the first blood serologic examination. During the same period 1,078 cases of syphilis were diagnosed, so that these 335 patients comprised 31 per cent of the actual cases of syphilis admitted. This group was chosen for the present study without further criteria of selection. Early syphilis of less than two years' duration was excluded because such cases would present more of a question of adequacy of therapy than a serologic problem. During the same period of time approximately 40,000 specimens of blood

SEROLOGIC DISCREPANCIES—CRAWFORD AND RAY

Jour. A. M.
Nov. 4, 19.

were tested in the hospital laboratory; 21,073 of these were on new cases admitted to various departments. By a thorough investigation of the 335 patients with late syphilis exhibiting a positive Hinton and a negative Wassermann reaction, it was hoped that a base line could be established as to the meaning of such a serologic status. They were considered especially in the light of diagnosis, activity of syphilis and need of further

evidence was gathered, analysis revealed that the diagnoses were made as indicated in table 2. The average age of these 155 patients was 43.7 years. In ninety-six cases in which the duration was known the disease had been present for an average of 23.7 years. There were twenty-five patients with congenital syphilis whose average age was 24.7 years. Among the males with an average age of 50.4 years; the ages of fifty-one females averaged 42.3 years. Further study of the latent, active and congenital subdivisions revealed some pertinent information: It was of interest to note that of thirty-nine patients with evidence of activity of the disease the average duration in eighteen known instances was 21.5 years. Among ninety-one inactive cases, the average duration in fifty-three in which those observers who feel that syphilis does not actually become "latent" and that some therapy, if tolerated, should be continued as long as there is detectable reagin in the blood. Also it was found that the thirteen patients with active congenital syphilis averaged 25.3 years of age. This is indicative of the necessity of lengthening the time wherein many observers feel that active syphilis exists. We are inclined to agree with those who believe that there is no time, regardless of the duration of the infection, at which syphilis may be trusted to remain inactive. This may apply to congenital as well as to acquired cases. The older group of patients with congenital syphilis should not be therapeutically neglected merely because they have grown to maturity without disabling lesions.

The effect of previous treatment is illustrated in table 3. These calculations bear out the already proved fact that any treatment is better than none. Among the untreated cases 33 per cent were active, whereas of those with even less than twenty-five injections less than 15 per cent showed active syphilis. This group of cases, wherein much confirmatory evidence was found,

treatment. At the outset relatively few cases presented distinct evidence of syphilis; the positive Hinton reaction was the only reason for observation of the disease was seriously doubted. After more careful history taking, physical examinations, repeated serologic checks and other diagnostic measures, definite additional proof of syphilis appeared in nearly half of the cases. The final grouping of the series appears in table 1. The diagnosis of syphilis was made in groups A, B and C, in which each patient had three or more positive Hinton reactions. In groups D and E there was disagreement in blood reports. Each group will be considered separately.

Group A.—In this group of 155 patients positive evidence of syphilis was found, each case averaging 2.4 indications of the disease in addition to the positive Hinton reaction. In the history the additional evidence consisted of a story of a primary sore, secondary manifestations, tertiary lesions, disturbances of the central nervous system, miscarriages, stillbirths, interstitial keratitis or previous therapy. The family history included known syphilis in the husband or wife, child, sibling or parent. On physical examination the additional signs consisted of mucocutaneous scars, osseous lesions (septal perforations, saddle nose, dental changes and Charcot's joints), ocular lesions (pupillary changes, interstitial keratitis, optic atrophy, choroiditis), neurosyphilis. Laboratory evidence of syphilis other than the positive Hinton reaction included subsequent positive Wassermann reports, positive changes in the cerebrospinal fluid, x-ray evidence of syphilitic cardiovascular lesions and one autopsy showing syphilis. When all the

illustrated not only the value of routine serologic tests of the blood but also the importance of a good follow-up in establishing a diagnosis of syphilis. Group B.—The thirty-six patients in this group all had four or more positive Hinton reactions and presented in addition some suggestive evidence of syphilis. The blood Wassermann reaction remained negative in all cases. A summary of this group is presented in table 4.

Total	36

* Two cases also showed roentgenologic evidence suggesting cardiovascular syphilis.

The average age of group B patients was 47.1 years. Since the history and physical evidence were not conclusive, cases of congenital syphilis could not be definitely segregated. A suggestive history consisted of dubious genital lesions, indistinct eruptions, possible iritis, and miscarriages or stillbirths of doubtful significance. There was a suspicion of syphilis in some member of the family in one fifth of these cases.

Indecisive physical lesions were inconclusive scars, osseous changes, dental changes, facies, pupillary aberrations, dubious old choroiditis or optic atrophy, other suspicious neurologic lesions, questionable cardiovascular damage and gastritis. Additional investigations are given in table 5.

GROUP C.—The fifty-four cases included here were diagnosed as syphilis on the basis of persistently positive Hinton reactions alone. This seemed justified in the light of such observers as Moore,⁷ who stated that, if a precipitation test is reliable, a series of positive reactions must be considered of the same significance as a series of positive Wassermann reactions. The Hinton test appeared to fulfil this criterion and should mean syphilis when persistently positive, regardless of negative Wassermann reactions. Five or more positive reactions were obtained here in each case; no evidence other than this was afforded. The average age in this group was 46.3 years. Additional investigations are given in table 6.

After having studied and tabulated the first two groups of cases (A and B) there was no hesitancy in our minds about making a diagnosis of syphilis in group C. Yaws and leprosy could be eliminated without difficulty; malaria was ruled out as far as possible by the anamnesis. The five blood examinations which gave consistently positive results were done over an average period of 9.8 months in all cases. This time factor should rule out the few diseases which are thought to cause a temporary positive reaction. The cases in this group comply with the criteria generally used to denote true latent syphilis.

GROUP D.—In this group there were forty-two cases that have not been classified. It was impossible to decide whether these patients had syphilis or were free of the disease. After the initial positive Hinton reaction the reports vacillated repeatedly. There was nothing in the personal or family history to suggest syphilis, nor was there a story of any disease which might have given rise to a "false positive" report. No physical evidence was found to suggest syphilitic damage. The

average age was 40.2 years. These patients have been followed for an average period of 10.2 months each. A summary of the data in this group appears in table 7.

Disagreements in the blood serologic reports were pronounced in this group. Additional checking by sending split samples simultaneously to two laboratories did not settle the question in these cases because of the failure of the results to coincide. This fact is demonstrated in table 8.

An example of the type of case encountered in this group is given in table 9.

It is possible that many of these patients had syphilis and perhaps some did not. From the clinical standpoint there was no way to decide. From a purely serologic aspect the discrepancies in reports precluded an accurate decision. It seemed that ten months should be long enough in which to decide whether most patients had syphilis, but when the data given were considered from the practical point of view the problem was not always clear.

GROUP E.—It was felt that in all probability the forty-eight patients in this group did not have syphilis. In each case there was a single positive Hinton reaction followed by several negative reactions. The initial positive reaction was followed by three or four negative reactions over a period of 10.5 months average time. Here again there was no history or physical evidence of syphilis in any case. The average age was 38.4 years. Every attempt was made to rule out any condition which might possibly have given rise to a tem-

porary false report, since haptens or "partial antigens" are thought to cause such reactions in some diseases. Table 10 presents the data on these patients. Serologic discrepancies were less pronounced in this group, as is reflected in table 11.

The question of "false positive" reactions arose in this group, and the series of subsequent negative tests in these cases indicated such a situation. These forty-eight patients comprised 13.7 per cent of the 335 cases

7. Moore, J. E.: The Modern Treatment of Syphilis, Springfield, Ill., Charles C. Thomas, 1933, p. 465.

studied, which was an undue number of false positive reactions for a test which has stood high in the conferences on serologic tests recently held. When computed on the basis of the state laboratory reports alone, in which only three positive reactions were obtained, less than 1 per cent of false positive reactions would exist. This was in agreement with the accepted status of the Hinton test. Some degree of error exists, however, in that not all cases were checked by the state laboratory. This situation implies that the Hinton test

reports on these ninety patients was 171. If computed on the basis of this number of tests against the total number of blood specimens examined by the laboratory during this period, approximately the same percentage of false positives is calculated.

The occurrence of false positive reactions can be attributed with certainty to such oriental diseases as yaws, relapsing fever and trypanosomiasis. Leprosy and malaria show false positive reactions less often. Hyperpyrexia, hemorrhagic diseases and jaundice are highly controversial. All these conditions were ruled out as far as possible in the present study. When a case showed occasional positive results interspersed among several negative ones, it may have been due to a fluctuating and very low reagin titer. Some good authorities construe such cases as being definitely syphilitic. Other observers feel that these serums contain some unknown substance which may be detected by a given test and that in the absence of clinical corroboration there is no syphilis present. There were nineteen cases in group D which exhibited this vacillating type of serologic status. Perhaps these were the only truly false positive cases. The rest of group D showed two

as done in the laboratory at the Massachusetts General Hospital was lacking in specificity. A tabulation of the chronologic occurrence of these false positive reactions, compared with the number of reports received per month, showed a direct ratio of incidence. That is, more were found in those months during which most of the cases were picked up.

This group showed the value of comparative serologic data between laboratories, even for the better hospitals. It also emphasized the absolute necessity of checking and rechecking a positive serologic reaction of the blood when other evidence is lacking.

"FALSE POSITIVES"

In order to compute the true percentage of false positive reports it was necessary to use the total number of new bloods tested in the laboratory during the

twenty-four months which this study included. There were 21,073 new patients who had serologic examinations of the blood during this time. To allow for the widest possible margin of error, all of both groups D and E were included, which made a total of ninety possible cases, which would be 0.42 per cent of false positives. The total number of positive and doubtful

or more positive or doubtful reactions followed by several negative reactions. It is possible that such patients showed a fading reagin titer just at the time at which it passed below a detectable level. A mistaken report or technical error occurring twice per case seemed most unlikely in so many instances.

The cases in group E, however, were in all probability merely falsely positive in the sense of "technical errors." A single positive reaction was followed by repeated negative reactions in each instance. Possible disease causes of a temporary false positive reaction were ruled out. Technical errors in such cases may be due to improper technic in the performance of the test, the skill of the individual technician, human fallibility in reading the tests, errors in labeling the tubes and mistakes in reporting the results. The occurrence of only forty-two such cases among 21,073 new serologic examinations provided the extremely low figure of 0.2 per cent in the two year period. Other situations that give rise to false positive or anticomplementary reactions in the complement fixation tests do not need to be considered here. These include bacterial or chemical contamination, the presence of a high concentration of a drug in the serum and an excess of native amboceptor. Many such factors which may inhibit complement fixation have no effect on the flocculation phenomenon and hence may be disregarded.

SEROLOGIC DISCREPANCIES—CRAWFORD AND RAY

1719

SUMMARY

Of 2,862 new patients admitted to the syphilis clinic at the Massachusetts General Hospital in a two year period, 335 late cases showed a positive Hinton and a negative Wassermann reaction. This group was studied exhaustively for additional evidence of syphilis. Nearly 50 per cent of these patients were found to exhibit a history or physical or laboratory evidence of the disease along with a repeatedly positive Hinton reaction. Another 25 per cent of these patients were diagnosed as syphilitic on the basis of a persistently positive Hinton reaction alone. In 12.5 per cent of the 335 cases a vacillating serologic reaction and lack of other evidence created indecision as to the presence or absence of syphilis. In the remaining 14.3 per cent of these cases the one initial positive reaction followed by repeated negative reactions was held to be a technical error.

The average age of the entire group was 42.8 years. The known average duration of syphilis in the clinically active group was 21.5 years in acquired cases. The average age of congenital syphilitic patients with active disease was 25.3 years, the eldest of whom was 30.

False positive reports were computed to allow for the widest possible margin of error. All undecided cases and all technical errors were included. Comparing this number to all new specimens examined by the laboratory during the time of the study, a figure of 0.42 per cent of false positives was obtained. This corroborated clinically the high degree of specificity attained by the Hinton test in congresses on serologic tests.

ABSTRACT OF DISCUSSION

DR. C. GUY LANE, Boston: The paper of Dr. Crawford and Dr. Ray adds to the evidence, if any is necessary, of the value of serologic tests in the detection of syphilis. Secondly, this work indicates the frequency with which confirmatory evidence can be found on careful study. We are impressed with the development of other manifestations of syphilis when patients with positive serologic reaction are examined carefully, and the authors have given us additional evidence of the possibility of the detection of such manifestations. In this particular series, some 50 per cent of the cases in which a positive serum reaction of the blood is present in the beginning can be taken out of the group of latent cases and diagnosed as symptomatic tertiary cases by the finding of other evidence. These figures also emphasize the importance of the latent group of syphilis today. While there are only some 14 per cent of true latent cases in this series, a review of the records in our clinic at the Massachusetts General Hospital over a five year period in which some 2,800 cases have been diagnosed as syphilis discloses that about 1,600, or 60 per cent, are diagnosed as latent syphilis. This study also shows again the unreliability of a single serologic examination. This fact must be reiterated to general practitioners, to other physicians and to the public as well. A press release of the Public Health Service the other day depicted premarital and antepartum serologic examination or blood test without reference to other examination or the need for checking up on those particular tests. The same flaw appears in the premarital and antepartum laws in the various states. There should be equal emphasis at least on further examination and further check-up of cases in which a single serologic positive is found. Finally this paper emphasizes the desirability of more than one type of test in our judgment of cases. For example, take the figures of our own clinic, with about 1,000 cases a year admitted for examination with reference to syphilis. Here are about 350 cases of serologic discrepancy in a two year period, a rather large percentage of cases in which a discrepancy has arisen. Therefore a test by a second method is of value in that it may in the first place aid the diagnosis by agreement; secondly, the second test may point to the diagnosis by the development of other evidence perhaps because of the mere positivity of the

second test and a negativity of the first test; and thirdly, the mere fact of the disagreement between the two tests may lead to a further detailed examination which may be entirely negative, and therefore the patient can be discharged because of the lack of evidence.

DR. G. V. KULCHAR, San Francisco: Drs. Crawford and Ray have well emphasized the necessity for repeated serologic examinations for the diagnosis of syphilis in the absence of clinical evidence. That is a fact that needs reemphasis. One would expect every case that gives a positive Hinton reaction to give a positive Wassermann reaction. This is not true, and it is explainable on the fact that the Hinton test as shown by the serologic ratings is much more sensitive than some of the older Wassermann tests. Does a positive Hinton reaction always mean syphilis? I have shown that there is a reagin-like substance in the serum of normal persons. Accepting that, it seems conceivable, though the data are not convincing as yet, that some intercurrent condition such as diabetes, menstruation or infectious mononucleosis fever may cause an increase in this reagin substance such as occurs following the injection of neoarsphenamine in nonsyphilitic persons to bring it up well within the range of positivity to the ordinary serologic test. I think this may explain the positive, transitory-positive Wassermann reactions that are observed during febrile states, in tuberculosis, and particularly in diabetes, in infectious mononucleosis. There is another angle. The frequent positive Wassermann reaction noted in malaria in the absence of syphilis is thought to be due to a reversal of the normal serum albumin-globulin ratio. A reversal of this serum albumin-globulin ratio, of course, takes place in other diseases. Changes in the serum albumin-globulin ratio occur in lymphopathia venereum. Lymphopathia venereum is one of the diseases reputed to have given a false positive Wassermann reaction. So we must look on the Wassermann test not as a specific but as a nonspecific test, which, like all nonspecific tests, is subject to error. Does a positive Hinton reaction necessarily mean active syphilis in a syphilitic patient? Now the studies of the Cooperative Clinical Group I think have indicated pretty definitely the benignity of late latent syphilis. Taking this along with the studies of Bruusgaard, there seems no great need of treating patients in late latency. In a person who is first seen twenty years or more after his infection, in whom the cerebrospinal fluid is negative, who is long past his period of infectivity and who through fluoroscopy and as far as one can go through physical examination presents no evidence of cardiovascular syphilis, we know his chances of developing a serious lesion from syphilis are relatively slight. So it does seem rather unnecessary to subject these patients to the hazards of treatment. Their possibilities of going through life without any evidence of syphilis so far as their physical well being is concerned are relatively good and the occasional patient who will develop a tertiary skin lesion does not justify treating every one of these patients.

DR. CHARLES R. REIN, New York: Drs. Crawford and Ray have again shown the importance of more sensitive serologic tests for the detection of syphilis. With the use of such tests they were able to detect cases of serologic syphilis which would have passed undiagnosed with the less sensitive tests. Recent serologic conferences held in the United States have demonstrated that there are at least five tests commonly used in this country which possess satisfactory specificity and adequate sensitivity. Dermatologists, however, should encourage the development and use of still more sensitive tests with satisfactory specificity by serologists. Such tests would detect more cases of so-called seronegative syphilis. The interpretation of the results obtained with such tests should be made by specialists.

DR. ARTHUR SCHUCH, Dallas, Texas: One word of criticism can be offered in spite of the fact that this is an excellent study: the serologic tests done in this particular study were based on comparatively few standard serologic tests. I mean the study as presented by the authors was based on the Hinton flocculation test and some Wassermann procedure. There are at least five standard serologic tests—the Kolmer Wassermann, the Hinton, the Kline, the Kahn and the Eagle. To base a study on two of the five and draw the conclusions that have been drawn seems specious. For the last few years we in Dallas who have been working with syphilis patients have used as a routine at

least three of these tests, and incidentally the technic is exactly as described by the originators, namely Kolmer, Kahn and Kline, and in the last two years we have added to that the Eagle complement fixation test and Eagle flocculation test. Now our routine procedure is to do not two or three sero-diagnostic tests on the blood but five in parallel. This has taught us a few things. It has taught us much about the relative sensitivity of these various tests. It has taught us something about false positive tests in what we think are apparently normal individuals. I am talking from the standpoint of the clinician and not from the standpoint of the serodiagnostician. At the serologic conference in Hot Springs last fall the clinicians were in the minority. Here the laboratory diagnosticians are in the minority. So I think it is a matter of one's point of view as to whether we regard group C, D and E the authors had on slide 1 in the doubtful group, or whether we include just group D and E. Group C was the group in which the diagnosis of syphilis was made solely on a positive Hinton test or a very sensitive flocculation test for syphilis. It will take observation over a long period of years to determine whether group C, as the authors presented it, did have syphilis or did not. The group of individuals that Dr. Ryan spoke about indicating that it all depends on how sensitive a serologic test is as to whether or not it has prognostic import, with special reference to early syphilis, I think can be placed to one side. We have dark field examination to help us there make a definite diagnosis. The important group to consider is not the early syphilitic patient who is beginning to go into serologic positivity, but the enormous group that Dr. Lane spoke of. In my experience it is at least 60 per cent of our entire clinic clientele, and in the last two years we have thoroughly examined, not merely serologically and cursorily speaking from a clinical standpoint, 5,400 new patients with syphilis.

DR. G. MARSHALL CRAWFORD, Boston: Thank you for this generous discussion. Dr. Lane brought out two points that I didn't have time to emphasize: the matter of having several tests to establish the diagnosis and also to use different laboratories. I am also indebted to Dr. Kulchar for mentioning the reagin-like substance. I covered that in one sentence, saying that some men believe there is a substance which will occasionally show positives by certain tests. The elaboration by Dr. Kulchar was quite enlightening. I should like to repeat that the observation of these cases extended over a period of nine to ten months, so that temporary causes of an increase in their reagin-like substance should be eliminated. Whether a positive Hinton reaction means activity of syphilis and whether these patients should be treated were points I expected to see raised and was glad to hear. We do not feel that all these patients should be given intensive therapy. It has been our policy to treat only definitely active syphilis intensively and the others on an intermittent plan. Some very notable observers say that the human mechanism is not capable of conquering the syphilitic infection without help. We usually give them a short course once or twice a year. The hazards of the complement fixation test were also mentioned; they are largely avoided by the flocculation or precipitation test. I was glad to hear Dr. Rein mention the possibility that there is no seronegative stage. As long as there is some reagin present there must be something going on to produce that reagin. Dr. Rein may be forecasting the day when we shall simply make a diagnosis of syphilis and disregard stages except for infectiousness. Dr. Schoch's comments were very apropos. We are envious of him, having five serologic tests at his command. We do a routine Hinton and when that is positive always do a Wassermann; when there is a question we get as many checks as possible in another laboratory. While we don't think that some of our conclusions are far fetched on a few tests, they certainly could be improved if we had more. I should like to quote a few figures, as yet unpublished, from the last Serologic Congress. The Hinton test was done by five laboratories and there was not a single false positive or false doubtful from any of the five laboratories. There was no other test showing a complete absence of false positives. The Hinton test was 83.9 per cent sensitive on known positive specimens. The Kline exclusion test was close to that and the other five tests submitted to that congress were grouped in the 70's of percentage.

ACUTE PERFORATIVE DIVERTICULITIS OF THE COLON IN YOUNG PERSONS

CARL BEARSE, M.D.

BOSTON

Based on reports of unselected postmortem examination¹ and on x-ray studies of the gastrointestinal tract of patients with abdominal symptoms,² the incidence of diverticulosis of the colon averages about 5.9 per cent. The average incidence under the age of 30 years is about 0.31 per cent of all diverticulosis patients;³ therefore, the frequency of diverticulosis in persons under 30 years of age would be about 18 per hundred thousand of population.

In an average of about 15 per cent of patients with diverticulosis diverticulitis develops,⁴ and approximately 21 per cent of these require surgical intervention,⁵ or about 3 per cent of diverticulosis patients. For the entire population the incidence of operation would be about 186 cases per hundred thousand of population, and for persons under 30 years of age, diverticulitis requiring operation would occur in no more than 5.7 patients in 1,000,000 of population.

It is possible, however, that diverticulosis and diverticulitis occur more frequently in young adults than has been indicated by these reports. Postmortem studies do not portray the true incidence of diverticulosis in young persons, since there is only an approximate mortality of 0.4 per cent of the population who are under 30 years of age.⁶ Likewise, the facts obtained from x-ray studies of the gastrointestinal tract are open to criticism. The average age of patients who have x-ray examinations made of the gastrointestinal tract has been given as 45 years.^{2c} Diverticula may not be visible unless special efforts are made to demonstrate them, and repeated x-ray examinations of the gastrointestinal tract may be necessary. To ascertain the approximately correct incidence of diverticulosis in persons under 30 it would be necessary to have x-ray studies of the gastrointestinal tract made for diverticula of all persons during their first three decades of life.

Furthermore, Judd and Pollock⁷ reported that of 118 operations for diverticulitis two, or 1.7 per cent, were performed on patients under 30 years of age. Also, in the course of my own private practice I have operated on three young adults for perforated diverticulitis with abscess, two of these patients being operated on within a period of two years.

REPORT OF CASES

CASE 1.—Mrs. J. P., aged 30, a housewife, admitted Jan. 21, 1925, had been taken ill five days previously with vomiting and constant abdominal pain, which was localized to the left lower quadrant. The patient was rather short and obese. The temperature was 102 F. There was considerable tenderness but no spasm in the left lower quadrant of the abdomen; no masses could be felt. Directions were given regarding the nonsurgical management of acute diverticulitis of the colon. Three days later the temperature was 102 F. and the pulse rate 120. An exquisitely tender mass the size of a large grapefruit was palpated for the first time in the left lower quadrant of the abdomen.

Operation was done the following morning. The mass consisted of omentum, adherent to the sigmoid, which was greatly thickened, particularly on the mesenteric border, and was covered with much fibrin. Associated with the mass was an abscess cavity containing about 8 ounces (240 cc.) of foul smelling pus. This was aspirated, and drainage was instituted. The patient made a satisfactory convalescence and was discharged from the hospital thirty days after operation. Gastrointestinal roentgenograms three and one-half months after the operation showed a diverticulum of the sigmoid.

CASE 2.—J. M., a man aged 23, admitted June 12, 1936, complained of intermittent abdominal pain of three weeks' duration which came on suddenly in the region of the umbilicus. He complained of diarrhea and vomiting on the day of the consultation as well as the day before. X-ray studies of the gastrointestinal tract showed moderate dilatation of several loops of small intestine; no diverticula of the colon were visible but the pattern of the mucosa seemed to be accentuated. A barium sulfate enema had been given and fluoroscopic examination showed tenderness at the junction of the descending colon and sigmoid. The patient was well developed and well nourished. The temperature was 99.6 F. Examination of the abdomen revealed exquisite tenderness and resistance at the left lower quadrant. Rectal examination disclosed a mass that could just be reached by the examining finger.

At operation a moderate amount of straw-colored fluid was found in the peritoneal cavity. The descending colon was adherent to the lateral parietal peritoneum, where there was a mass the size of a baseball. Within this mass was an abscess cavity from which about 4 ounces (120 cc.) of foul smelling pus was aspirated. A cigaret wick was placed into the cavity. The convalescence was fairly uneventful and the patient left the hospital on the thirty-seventh postoperative day. Roentgenograms of the gastrointestinal tract six months after the operation showed a diverticulum of the descending colon.

CASE 3.—Miss E. G., aged 19, a bookkeeper, admitted March 26, 1937, complained chiefly of abdominal pain, which after onset four days previously had localized to the right lower quadrant. Two days before admission she had an evening temperature of 101 F. There was no nausea and no vomiting. The patient was well developed and well nourished. The temperature was 100.5 F. Examination of the abdomen revealed tenderness, resistance and an indefinite fulness to the right of the umbilicus. Rectal examination was negative.

Operation revealed a mass the size of a tennis ball in the region of the ascending colon. Within the mass was an abscess cavity from which about 1 ounce (30 cc.) of thick, foul smelling pus was aspirated. A cigaret wick was placed into the cavity. The convalescence was relatively uneventful, and the patient was discharged from the hospital three weeks later. Roentgenograms of the gastrointestinal tract ten months after the operation showed a diverticulum of the ascending colon.

COMMENT

The causation of diverticulosis is still obscure. Although various explanations have been offered for the development of diverticulosis, such as old age, constipation with increased gaseous pressure within the colon, excessive fat or emaciation, and even a disturbance of the sympathetic nerves of the colon,^{2a} it

seems that the most applicable cause in young persons is an inherent weakness in the structure of the colon, which is usually at the point of entrance or exit of the blood vessels.⁸ The possibility of diverticula being congenital should also be considered, since cases have been reported in children and even in infants.⁹

In young adults, as in older patients, diverticula rarely give rise to symptoms until there are inflammatory changes. These changes may be brought about by trauma,¹⁰ such as repeated straining at stool, enemas given at high pressure, the use of drastic cathartics, and strenuous exercise. Food may also be a factor in causing diverticulitis;^{2a} red meats, for instance, may increase the bacterial activity within the intestine, and potatoes and milk may cause irritation by forming a relatively large mass. The possibility of an infection from a distant focus¹¹ should also be considered.

In diverticulitis the symptoms may closely resemble those of acute appendicitis. Pain, the outstanding symptom, may vary in intensity and may be intermittent or constant. Nausea and vomiting may be present. There is always localized abdominal tenderness and at times rigidity as well as distention. The temperature is usually elevated and there is an accompanying leukocytosis.

When diverticulitis involves the ascending colon, as in case 3, the diagnosis may be confused with an appendical abscess until the abdomen is opened. If, however, the lesion is on the left side a correct pre-operative diagnosis is frequently made. At times an abscess associated with diverticulitis can be felt by rectum. Fluoroscopic and sigmoidoscopic examinations may be of help in making an accurate diagnosis but are not without risk; if too vigorous, rupture of the abscess may result.

In early diverticulitis, that is, before perforation and abscess formation, inflammation may subside under nonsurgical management. This treatment should consist of rest in bed, practically nothing by mouth for a day or two, and ice bags or heat to the seat of pain. The heat may include short wave diathermy, electric pads, hot packs, Elliott treatment or rectal irrigation of warm physiologic solution of sodium chloride or olive oil. After the inflammation begins to subside, olive oil (2 or 3 ounces) or liquid petrolatum may be given by mouth, and later food, the diet at first being practically free of residue. Subsequently the patient should be put on an anticonstipation diet and given oil or agar by mouth.

If an abscess is present when the patient is first seen, as in the cases reported, or if in spite of medical treatment perforation and abscess formation take place, operation for the drainage of the abscess is indicated. If obstruction is present, cecostomy should also be done and, if the obstruction persists after the acute inflammation has subsided, resection of the obstructed area may be necessary.

Following recovery from an operation for perforated diverticulitis, the patient should be advised that

diverticulosis is still present. In order to avoid further development of diverticula or a recurrent diverticulitis, large doses of kaolin,¹² bismuth subnitrate or barium sulfate¹² once or twice a week may be helpful. Particular attention should be given to regularity at stool; agar may be taken for bulk and soft stools.^{3a} An effort should be made to improve the intestinal flora.^{2b} It would be well for the patient to exclude from the diet coarse and indigestible foods and to include cooked fruits and finely chopped vegetables.^{3a}

SUMMARY

1. Diverticulosis and diverticulitis of the colon probably occur more frequently in young persons than reports would indicate.

2. In this report young adults required operation for perforated diverticulitis of the colon with abscess.

EPIDEMIC ENCEPHALITIS IN
NORTH DAKOTA

PAUL J. BRESLICH, M.D.

PAUL H. ROWE, M.D.

AND

WILLIAM L. LEHMAN, M.D.

MINOT, N. D.

During July, August, September and October 1938 an epidemic of acute encephalitis, which clinically resembled the St. Louis type, was observed in North Dakota. According to information supplied by Dr. John Cowan, of the North Dakota Department of Health, 101 instances were reported, of which fifty-two occurred in Minot and the surrounding rural territory, which includes the ten counties in the northwestern portion of the state. Twenty-three of these patients were cared for in Trinity Hospital by the members of the medical staff, and the material of this report was obtained from their clinical records. Nine entered the hospital from Minot, while fourteen came from farm homes located within a radius of 65 miles of the city. The rural patients lived from 10 to 120 miles apart, and in only two instances did more than one patient come from any single locality.

Nineteen patients were adults and four were children. Arranged according to age groups, the incidence among adults was evenly distributed from 20 to 70 years. Nine of the adults were men and ten were women. The four children ranged from 2 months to 8 years in age. Two were boys and two were girls. Most of the city patients were engaged in business or professional pursuits, and one was a nurse who had cared for patients ill with encephalitis. The severity of the symptoms was not related to age and was just as marked in the younger as in the older patients. Five died of the illness and were respectively 25, 26, 36, 57 and 60 years of age.

The illness was characterized by an acute onset with generalized severe headache and fever. The temperature when first taken at home ranged from 101 to 105 F., the average being about 102 F. The commonly used analgesics gave no relief from headache. The patients complained of severe generalized muscular pains and backache. Chills and chilly sensations

occurred when the temperature elevation was marked. Nausea and vomiting occurred in about one half of the patients early in the illness. Dizziness and drowsiness appeared within the first three days, but in spite of the drowsiness the patients were unable to sleep. After the fourth day, coarse or fine muscular tremors of the arms and face were present in about three fourths of the adult patients. The tremors were of the intention type and were absent at rest.

The symptoms of individual patients varied considerably. One became comatose on the first day of the illness while the mental symptoms of ten others did not progress to a state of delirium. Eight of the adult patients became irrational and delirious on the fourth or fifth day, and this condition was followed by coma within two days of all but one of these patients. For a time they could be aroused momentarily to take food, but later coma became deeper and incontinence of urine and feces occurred. Coma was a grave prognostic sign and five of the eight comatose patients died, four within two days after the onset of coma and one after eleven days. Two of the five had repeated convulsions before death and one had a right hemiplegia which could not be explained by cerebral hemorrhage or thrombosis at the postmortem examination. A third patient died of paralysis of the respiratory center, the respirations gradually slowing to 4 or 5 a minute. In only one instance was there a terminal bronchopneumonia.

In the children the onset was sudden with high fever. Vomiting, nervous irritability and convulsions were the most frequent symptoms, while coma of only one patient occurred. Spasmodic muscular contractions of the right arm and leg of one infant were noted. Recovery of children was rapid, and the course of the illness was several days shorter than that of adults.

Most of the patients had been ill three or four days before admission to the hospital. Physical examination disclosed no constant changes in the heart, lungs or abdomen. Rigidity of the neck, the most characteristic physical finding, appeared early in the illness and was present in fifteen cases. This sign was elicited by any passive effort to bring the head forward on the chest. Coarse intention tremors of the hands and face, particularly of the lips, were observed in all but seven cases, and in four there was slurred speech, apparently related to the tremor of the lips and tongue. The abdominal reflexes were absent in ten instances and later became absent in two more. The Kernig sign was positive in six of the cases in which there was rigidity of the neck. The Babinski reflexes were positive in only four cases and varied from time to time. There were no characteristic abnormalities of the patellar and achilles tendon reflexes. Lateral nystagmus was present in two cases, and in two others a fixation nystagmus was demonstrated. In one of the latter there was a transient divergent squint.

The temperatures on admission to the hospital ranged from 100.6 to 105.6 F., most of them being between 102 and 104 F. In those cases in which recovery occurred the temperature remained elevated from three to seven days after the onset and then subsided to normal within two or three days. The average duration of fever was about eight days. The pulse and respiratory rates were increased proportionately to the temperature.

Recovery from delirium, somnolence, muscular tremor and rigidity of the neck were complete within

From the Medical Service and Laboratory of Trinity Hospital and the Northwest Clinic.

one week after the temperature became normal. In one instance muscular tremor persisted for about six weeks. The average duration of the illness before convalescence was well established was fifteen days.

LABORATORY EXAMINATIONS

The average white blood cell count was 12,200, the lowest being 5,200 and the highest 22,700. The differential blood counts disclosed no constant change.

Fig. 1.—High power microscopic field demonstrating perivascular round cell infiltration.

Examination of the urine revealed albuminuria in eleven instances, the amount varying from 10 to 800 mg. per hundred cubic centimeters, but in most cases it was not more than 50 mg. per hundred cubic centimeters. Two patients showed traces of dextrose in the urine, and a third showed a large amount of dextrose with acetone and diacetic acid. This patient's blood sugar was 240 mg. per hundred cubic centimeters and death occurred on the ninth day of illness, although hyperglycemia and glycosuria were controlled by insulin.

In one fatal instance, the blood culture was repeatedly positive for the hemolytic streptococcus, and in four cases in which typhoid was suspected the Widal test was negative.

The average white cell count of the spinal fluid was 130, and it varied from 2 to 525 cells in individual instances. In adults about 80 per cent of the cells were lymphocytes and the rest polymorphonuclear leukocytes, while in children about 50 per cent of the cells were polymorphonuclear leukocytes. The spinal fluid sugar content, not including that of the diabetic patient, ranged from 45 to 104 mg. per hundred cubic centimeters, the average concentration being 72 mg. per hundred cubic centimeters. The cerebrospinal fluid pressure with the patient lying on the side ranged from 100 to 230 mm. of spinal fluid. The Nonne test was faintly positive in seven cases, and Lange's colloidal gold test was negative in five. The spinal fluid was cultured in seven instances and found sterile.

PATHOLOGY

Postmortem examination was performed on all five patients who died. The characteristic pathologic changes were limited to the central nervous system, and examination of the thoracic and abdominal tissues disclosed only such changes as might have been found in any severe toxic illness. When the dura was reflected from the brains a marked hyperemia of the leptomeninges was the most noteworthy change. There was

some flattening of the cerebral convolutions and narrowing of the sulci, and on surfaces made by cutting, the tissue of the brains was pink.

Histologically the leptomeninges were diffusely infiltrated with lymphocytes, although plasma cells and epithelioid cells were occasionally seen. The infiltration was most marked over the base of the brain, while over the vertex the cellular exudate was most abundant opposite the cerebral sulci. The small blood vessels of the brain and of the leptomeninges were widely distended with erythrocytes. Thrombi were found in a few small arteries in the basal ganglions of one brain and were associated with small recent hemorrhages in the surrounding tissue.

The most striking microscopic change was a marked perivascular round cell infiltration. This occurred in all parts of the brain but was less marked in the cerebral cortex and medulla than in the basal ganglions, pons and medulla oblongata. Occasional lesions were found in the cerebellum. The round cell exudates occupied the so-called Virchow-Robin spaces and only rarely were round cells found between the blood vessels and the brain substance. The cells were chiefly lymphocytes but plasma cells, epithelioid cells and polymorphonuclear leukocytes were occasionally identified.

A second characteristic change consisted of aggregates of mononuclear cells widely distributed in the gray and white matter of the brain. These lesions varied in size but ordinarily were not more than 250 microns in the greatest diameter. The mononuclear cells were apparently of glial origin. Their nuclei were rather large, round or oval, and often indented. The cytoplasm was scanty, irregular in outline and poorly defined. In the larger cell aggregates occasional lymphocytes were identified. The cell masses were not related to the vascular lesions and occurred independently of them.

Fig. 2.—High power microscopic field from region of glial proliferation.

phocytes were identified. The cell masses were not related to the vascular lesions and occurred independently of them.

In all five brains degenerative changes of the large nerve cells were observed in the basal ganglions and pons, medulla oblongata and occasionally the cerebral cortex. The changes consisted of swelling and rounding off of the cell bodies with disappearance of the Nissl granules. The nuclei of these cells stained more deeply than normal, and the nuclear outlines were indistinct. In some no nuclear substance was visible and the rounded or irregular cell remnants were stained deep pink in hematoxylin and eosin preparations. Such cell

remnants were most frequently found in or near the regions of glial cell proliferation but were also found in the more normal tissue.

An unusual feature of the histologic preparations from the basal ganglions, pons and medulla oblongata was the presence of foci of demyelination in which the normal brain tissue was replaced by a pale staining spongy fibrillar mass. These lesions were no larger than a miliary tubercle. Many of them were densely infiltrated with mononuclear cells similar to those found in the regions of glial proliferation, but it was not unusual to find foci containing almost no mononuclear cells. The lesions were irregularly distributed in the tissue. Some were arranged along the course of the blood vessels, but others occurred as isolated lesions unrelated to the blood vessels. Foci of demyelination were not observed in the medulla or cortex of the cerebrum or cerebellum. The lesions were found in all five brains but the frequency with which they occurred varied considerably. They were numerous in three, while in the other two many microscopic sections were carefully examined before the lesions were demonstrated.

Fig. 3.—Low power microscopic field from lentiform nucleus, demonstrating region of demyelination.

In three brains marked glial proliferation, perivascular round cell infiltration and degenerative changes in the nerve cells were noted in the olfactory bulbs.

Serums from six patients who recovered were examined in two laboratories. Dr. Edwin H. Lennette, of the Department of Pathology of Washington University School of Medicine, St. Louis, reported that four of the serums failed to neutralize the virus of Western equine encephalomyelitis or of lymphocytic choriomeningitis. Three of the four failed to neutralize the St. Louis encephalitis virus, while the fourth on repeated tests gave equivocal results.

Serums from the same four patients in addition to two others were examined in the laboratories of the National Institute of Health, of the U. S. Public Health Service in Washington, D. C., and Dr. Charles Armstrong was kind enough to report that in only one instance were neutralization tests with St. Louis encephalitis virus strongly positive. This serum was from the same patient in whom equivocal results had earlier been obtained by Dr. Lennette. Serum from four of these six patients was found to contain neutralizing antibodies against the Western virus of equine encephalomyelitis.

COMMENT

Acute epidemic encephalitis, as it was observed in North Dakota in the summer of 1938, resembled that reported in the St. Louis region in 1933.¹ The symptoms, physical manifestations and clinical course were similar. The seasonal incidence and the distribution of the cases in the community were much the same.²

The pathologic changes in the central nervous system, however, differed from those occurring in the St. Louis patients³ in that small regions of demyelination were found in the basal ganglions, pons and medulla oblongata. Because of the difference in the pathologic condition it was suspected that the illness in North Dakota patients might be caused by a virus different from that responsible for the St. Louis epidemic. As already stated, the serum from only one of six patients who recovered neutralized St. Louis encephalitis virus.

In view of the fact that encephalitis in human beings has been reported as caused by the virus of both Eastern and Western equine encephalomyelitis,⁴ it is interesting to note that Western equine encephalomyelitis was prevalent in North Dakota in the summer of 1938. Serums from six of our patients who recovered were tested against the Western virus of equine encephalomyelitis, and Dr. Armstrong reported that the neutralizing antibodies were moderately positive in two instances and positive in two others.

The mortality in our series of patients was about 22 per cent. This figure is probably too high, since only seriously ill patients were brought to the hospital. The incidence of less severe acute encephalitis in the community could not be determined. The increased severity in the older age groups noted in St. Louis was not apparent in our patients.

In children the illness was first thought to be acute anterior poliomyelitis without paralysis, but later, because of the marked similarity of the clinical course to that in adults, the diagnosis was changed to acute encephalitis. Since all the children recovered, the pathologic changes could not be investigated.

SUMMARY

Twenty-three instances of acute epidemic encephalitis not previously observed occurred in North Dakota.

Clinically the illness resembled the St. Louis type of acute encephalitis.

Pathologically the North Dakota encephalitis differed from the St. Louis type in that foci of demyelination occurred in the basal ganglions, pons and medulla oblongata.

Serum from only one of six patients who recovered neutralized the virus of St. Louis encephalitis, while serum from four of these six patients neutralized the Western equine encephalomyelitis virus. The virus of lymphocytic choriomeningitis was not neutralized by serum from these six patients.

The mortality in the reported series was 22 per cent.

DESOXYCORTICOSTERONE ESTERS

CERTAIN EFFECTS IN THE TREATMENT OF
ADDISON'S DISEASE

JOSEPH W. FERREBEE, M.D.

CHARLES RAGAN, M.D.

DANA W. ATCHLEY, M.D.

AND

ROBERT F. LOEB, M.D.

NEW YORK

During the past decade there have been two material advances in the treatment of patients suffering from Addison's disease. The first of these was the recognition of the abnormalities of electrolyte metabolism present in addisonian patients and the correction of these disturbances primarily through the addition of large amounts of sodium salts to the diet¹ and also through a reduction in the intake of potassium.² The second advance came through the elaboration of extracts of the adrenal cortex,³ which are life sustaining, at least in adrenalectomized animals.

Despite the progress made through these contributions, the treatment of Addison's disease has continued to be only moderately satisfactory at best. In the past three years the isolation of a series of crystalline steroids of great physiologic activity from adrenal cortical material has been accomplished by Kendall,⁴ by Wintersteiner and Pfiffner⁵ and by Reichstein.⁶ This work aroused the anticipation that one of these active steroids might be synthesized in sufficient amounts to make possible the treatment of adrenal insufficiency in man. This hope has been realized in the synthetic preparation of esters of desoxycorticosterone by Reichstein,⁷ and the present report deals with the results obtained following their use in a series of thirteen patients with Addison's disease. These results are in general agreement with those reported by Thorn⁸ and his associates and by Cleghorn and his colleagues.⁹

EXPERIMENTAL

Observations were made of the effects of desoxycorticosterone esters¹⁰ on various blood constituents including sodium, potassium, calcium, chloride, bicarbonate, nonprotein nitrogen, serum proteins, sugar and cholesterol. The effects on the excretion of water, sodium, potassium, total nitrogen and riboflavin were studied, and observations were made on changes in hematocrit, serum volume as measured with the blue dye method of Gregersen and Gibson, and total interstitial fluid volume as determined by the sodium thio-cyanate method. Finally, in a number of instances the effects of desoxycorticosterone on the basal metabolic rate and carbohydrate metabolism were recorded.

In this study, six patients were placed on standard regimens in the metabolism service. Their diets were essentially constant as to the types and amounts of the various foodstuffs, caloric values and mineral content. These patients also received a constant fluid intake and

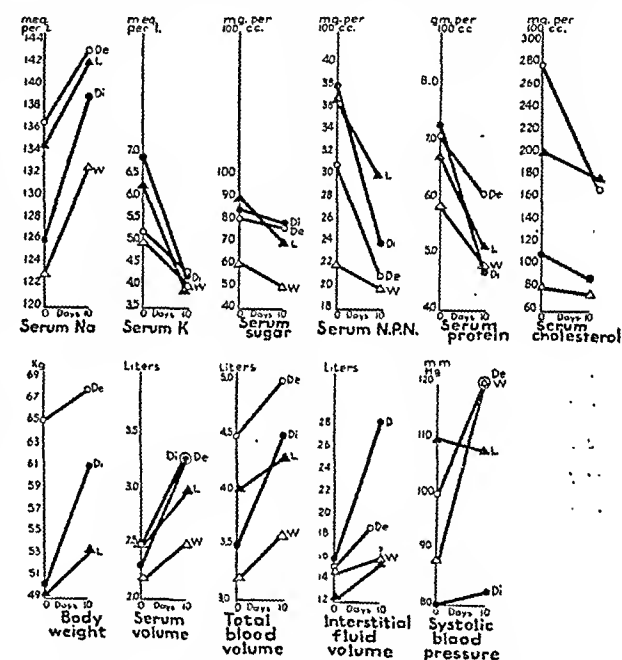

Fig. 1.—Summary of certain effects of desoxycorticosterone propionate observed after ten days' treatment of a group of patients with Addison's disease maintained on a standard regimen.

were given in addition to their food, which was prepared "salt free," a constant intake of sodium chloride. In addition to these rigidly controlled cases, observations were made on other addisonian patients who were allowed to eat and drink as they desired.

After a foreperiod of varying duration, the hospitalized patients received, as a rule, 25 mg. of desoxycorticosterone acetate or propionate daily for four days and then from 10 to 25 mg. daily for five days more. (The hormone, dissolved in sesame oil, was injected subcutaneously or intramuscularly once a day and each cubic centimeter contained 5 mg.) After this time the patients were allowed to eat as they desired and the dose of synthetic hormone was continued at a maintenance level. We have failed to detect any definite difference in activity between the acetate or propionate esters of desoxycorticosterone. The details of treatment are presented in the individual case histories.

10. The desoxycorticosterone esters used in this work were furnished by Roche-Organon, Inc. The term "doca" is employed as a contraction of the full chemical name.

RESULTS

The results are shown in part in the table and in figure 1 and can be summarized as follows:

Salt and Water Retention.—Desoxycorticosterone esters cause a striking retention of salt and water. The rate of retention of the sodium ion usually exceeds that of water, so that as a rule the serum sodium concentration increases to normal and is maintained at a normal level as fluid retention continues. In case 4 (fig. 2) water appeared to be retained more rapidly at first than the sodium ion, resulting in an actual decrease in the sodium level of the blood for three days. Following this the concentration rose to normal despite further water retention. In case 6, of extensive tuberculosis, it was never possible to raise the sodium concentration above 132 milliequivalents per liter although the retention of water was sufficient to cause pulmonary

hours and the chloride excretion underwent a comparable change.

As a result of these changes there were marked increases in the extracellular fluid volume in the various cases as measured by the sodium thiocyanate method. These increases were in general agreement with the gains in body weight except in case 1, in which repeated observations suggested an increase in extracellular fluid volume of 8.0 liters but a gain of only 3.3 Kg. in body weight. This discrepancy is not at present explainable. The data for salt and water retention in this case indicate that the validity of the thiocyanate figure is questionable.

The blood serum volumes increased between 0.3 and 1.2 liters during the first ten days of treatment in the six cases in which these measurements were made. These increases are in close agreement with the

† Figures in bold face type are following desoxycorticosterone propionate or acetate and represent maximal effects.

congestion, hydrothorax, generalized edema and a temporary elevation of venous pressure to 140 mm. of water.

The amount of salt and water retained varies greatly in different cases and cannot be correlated with the initial sodium or serum protein concentrations or with the initial plasma volumes. Patient 3 (fig. 3) gained 11 Kg. in ten days, during which time he received a total of 190 mg. of the hormone. In contrast, patient 1 gained but 2 Kg. in thirty days, during which time he received 725 mg. of hormone. Both of these patients received the same amounts of sodium and potassium salts in their diets.

Coincident with the retention of salt and water and gain in weight, there was in every case a considerable decrease in the urinary excretion of sodium, chloride and water. For example, in case 3 the urine output fell from an average of about 1,500 cc. daily to as little as 410 cc. during the period of administration of 15 mg. of hormone each day. The sodium excretion fell from the average control period level of 159 milliequivalents to as low a value as 28 milliequivalents in twenty-four

decreases in hematocrit and serum protein concentration and indicate that no significant change in red cell volume occurred.

No consistent alterations of albumin-globulin ratios occurred in the four cases in which this determination of the serum was made. These included the two cases in which the serum protein concentrations fell respectively from 7.3 to 4.7 and from 5.9 to 4.8 Gm. per hundred cubic centimeters.

Potassium Excretion.—Synthetic desoxycorticosterone esters cause a striking decrease in the concentration of potassium of the serum and frequently reduce it to abnormally low levels. Thus, in eight of nine cases the potassium concentration after treatment was lower than 4 milliequivalents per liter, the lower limit of our normal values. In no instance, however, did the potassium concentration fall below 2.9 milliequivalents per liter.

The urinary excretion of potassium increased on the first day of hormone injection in the six cases in which this was studied. Thereafter the potassium excretion was extremely variable. For example, in one case there

resulted an increase in excretion of potassium far in excess of that which could be accounted for by a decrease in concentration in the interstitial fluid and also greatly in excess of that which might have been liberated by cell breakdown as judged by a slight increase in excretion of nitrogen. In another case the excess potassium excreted could be entirely accounted for on the basis of that lost from the interstitial fluid alone. In a third case the excess excretion was even less than might have been anticipated from the decrease in serum potassium level.

Nitrogen Excretion.—The nonprotein nitrogen level of the serum decreases even when it is within normal limits at the beginning of treatment.

Total nitrogen excretion may not be affected, but as a rule there is a slight increase not exceeding 2 Gm. in the first two or three days of treatment.

respiratory quotients measured before and after two weeks of hormone treatment in this case were 0.85 and 0.78 respectively—a change of questionable significance. In another case two hypoglycemic episodes occurred during which the blood sugar levels were 40 and 38 mg. per hundred cubic centimeters. This patient had been receiving 10 mg. of desoxycorticosterone daily for more than two weeks. This dose was insufficient to raise the blood sodium level above 122 milliequivalents per liter, although it was enough to cause excessive fluid retention.

Blood Pressure.—The effect of desoxycorticosterone derivatives on blood pressure is undeniable, although it does not appear as promptly as do the effects on salt and water metabolism. In all of the thirteen cases the blood pressure reached normal levels in the course of two to four weeks and in three cases it has risen gradu-

§ After return to normal.

† Docea = Desoxycorticosterone acetate or propionate (Roche-Organon).

In the two cases in which determinations were made it appears that ammonia excretion increases within twenty-four hours after desoxycorticosterone has been administered.

Blood Calcium and Cholesterol.—The serum calcium concentration decreases following administration of the hormone. This was observed to be true in each of six cases in which determinations were made before and ten days after the initiation of treatment. This change may be attributed to hemodilution with its attendant decrease in serum albumin concentration.

The cholesterol content of the blood also decreases, probably as a result of hemodilution.

Carbohydrate Metabolism.—No evidence has been found to suggest that desoxycorticosterone esters have any effect on carbohydrate metabolism. The fasting blood sugar level is often as low or even lower after from ten to forty days of treatment. In case 1, in which 25 mg. of hormone was administered daily for thirty days, the fasting blood sugar level was 74 mg. and four hours after the ingestion of 100 Gm. of dextrose it was 46 mg. per hundred cubic centimeters. The

ally to 160/92, 160/110 and 146/108 respectively. It does not seem likely on the basis of the history that any of these patients suffered from hypertensive vascular disease before the onset of Addison's disease.

Miscellaneous Effects.—In addition to the objective changes described, all of the patients feel stronger and their characteristic early morning asthenia and nausea disappeared during the course of treatment with the synthetic hormone. No definite effect on pigmentation has been noted beyond that attributed to rehydration and no change in riboflavin excretion has been observed.

Effect of Progesterone.—In view of recent observations on the similarity of action of progesterone and desoxycorticosterone¹¹ in animals, their relative effects were compared in three cases of Addison's disease. The results in two of these are shown in figures 3 and 4. It is clear that the daily subcutaneous administration of

11. Thorn, G. W., and Engel, L. L.: The Effect of Sex Hormones on the Renal Excretion of Electrolytes, *J. Exper. Med.* 68: 299 (Sept.) 1938. Gaunt, Robert; Nelson, W. O., and Loomis, Eleanor: Cortical Hormone-like Action of Progesterone and Nonspecific of Sex Hormones on "Water Intoxication," *Proc. Soc. Exper. Biol. & Med.* 39: 319 (Nov.) 1938. Greene, R. R.; Wells, J. A., and Ivy, A. C.: Progesterone Will Maintain Adrenalectomized Rats, *ibid.* 40: 83 (Jan.) 1939.

progesterone in doses of 30 mg. given for seven or eight days was entirely without either subjective or objective effect. Whether larger doses might have had some effect is not known.

COMPLICATIONS

In view of the high degree of physiologic activity of desoxycorticosterone esters, it could be expected that overdosage might result in the appearance of disturbing complications. Indeed, ten of thirteen patients developed edema varying from mild and transient puffiness of the face and ankles to massive anasarca. Patients 3, 6 and 11 developed respiratory distress, tightness in the chest, a rise in venous pressure and a decrease in vital capacity associated with x-ray evidence of pulmonary congestion, as shown in the table. Patient 3 also developed striking dilatation of the right side of the heart (fig. 5). In this patient the rapid increase in blood volume from 3.6 liters up to 4.5 liters was associated with the development of hypoproteinemia, circulatory

basis for the dilatation of the heart, although mild hypertrophy was present.

The mechanism for the development of cardiac insufficiency in these three cases is not clear. A rapid and extensive increase in circulating blood volume is a possible factor, although in case 6 the increase in blood volume caused by the hormone was only 300 cc. at the time when the venous pressure was elevated and symptoms were most marked. The possibility of vitamin B₁ deficiency as an etiologic factor has been considered but, with the exception of relatively low excretion of thiamin in the urine, we have no evidence to support this idea.

REPORT OF CASES

CASE 3.—History.—M. D., a man aged 27, unmarried, a soda clerk, whose history prior to the present illness contained no significant facts, for about ten years had tanned easily and noticed that the tan did not fade normally. One year before admission he consulted a physician because of weakness, anemia (hemoglobin 75 per cent, erythrocytes 3,700,000) and he improved following treatment. The present illness was finally precipitated by a reaction to tetanus antitoxin given for a hand injury; after considerable vomiting he received a saline infusion with spectacular benefit and the diagnosis of Addison's disease was made. In spite of the use of salt and small amounts of adrenal cortex extract he continued to fail and a perirectal abscess accelerated this trend. He lost 19 pounds (8.6 Kg.) in the four months before coming to the Presbyterian Hospital. On admission he was thin, markedly pigmented both in skin and mucous membranes, and obviously ill; the blood pressure was 80 systolic, 40 diastolic, and there was acrocyanosis and a fistula in ano. There was no evidence of tuberculosis. His sedimentation rate on admission was 68 mm. in one hour, but he was afebrile. The basal metabolism was —8 on February 27. Chemical studies on admission showed the serum sodium 126 milliequivalents per liter, potassium 7.7 milliequivalents per liter, blood sugar 78 mg. per hundred cubic centimeters and nonprotein nitrogen 41 mg. per hundred cubic centimeters.

This was a typical case of Addison's disease, probably due to atrophy of the adrenals and complicated by a rectal fistula.

Treatment with Desoxycorticosterone.—The patient was placed on a constant diet with measured and constant intake of sodium (12.3 Gm.), potassium and water. He was then given 30 mg. of progesterone daily intramuscularly for eight days and no demonstrable effect was noted on weight, blood pressure, excretion of urine chloride or in serum electrolytes. He was then given 25 mg. of desoxycorticosterone subcutaneously for four days. His weight increased 1.7 Kg., the urine volume was halved and there was no marked change in urinary nitrogen. Urine chloride excretion was decreased 30 per cent, sodium excretion 60 per cent, and urine potassium excretion was increased about 60 per cent. Serum cholesterol decreased from 112 to 102 mg. per hundred cubic centimeters, serum sodium rose from 126 to 132 milliequivalents per liter, chloride from 100 to 104 milliequivalents per liter, bicarbonate from 20 to 23 milliequivalents per liter, serum potassium fell from 6.9 to 4.3 milliequivalents per liter, protein 7.3 to 5.6 per hundred cubic centimeters, nonprotein nitrogen from 38 to 30 mg. per hundred cubic centimeters. The serum sugar was not changed. The extracellular fluid volume rose from 15.9 to 19.8 liters. The hematocrit reading fell from 34 to 27.5 per cent cells. The blood pressure was not altered. The patient was then given between 10 and 15 mg. of desoxycorticosterone subcutaneously daily for the next seven days and gained 9.1 Kg. more weight. At this time there was marked edema of the face, saerum and ankles. The venous pressure was elevated (158 mm. water), the vital capacity was lowered to 1,250 cc. and he had developed an acute dilatation of the right side of

Fig. 2 (case 4).—Effects of desoxycorticosterone acetate and propionate.

embarrassment and edema. It was necessary to resort to the restriction of fluid and salt to do away with this "edema of adrenal origin." He improved promptly, and in the course of fourteen days his venous pressure dropped from 157 mm. to 80 mm. of water, his cardiac dilatation disappeared (fig. 6), his vital capacity rose from 1,250 cc. to 4,250 cc., and except for slight puffiness of his face and ankles his edema disappeared. It is of interest to note that after this improvement had taken place the circulating blood volume was still 4.5 liters.

In case 11, serious cardiac insufficiency associated with a rise in venous pressure to 250 mm. of water and a rise in arterial pressure to 160/110 mm. of mercury developed at a time when the patient was taking only 15 mg. of desoxycorticosterone every other day and from two to three teaspoonfuls of salt in his diet. The difference in the size of his heart before and after treatment may be seen in figures 7 and 8. Following phlebotomy and the limitation of salt and water the venous pressure fell but the patient succumbed with a terminal pneumonia. The details are described in the case record. Autopsy revealed no adequate organic

the heart (fig. 5). During this period the urine output was about one half of that in the foreperiod. The excretion of urine chloride varied but was usually below that of the foreperiod by about 45 per cent. Excretion of urine sodium was 30 per cent of that during the foreperiod and urinary potassium was about 20 per cent less than during the foreperiod. His serum sodium had risen to 138.6 milliequivalents per liter from 131.6, chloride to 107 milliequivalents per liter from 104, bicarbonate to 25.6 from 23.1 milliequivalents per liter. The serum potassium remained about the same after the first four days and at this time was 4.2 milliequivalents per liter. The serum

Fig. 3 (case 3).—Comparison of effects of progesterone and desoxycorticosterone propionate.

protein continued to fall from 5.6 to 4.7 per hundred cubic centimeters, the nonprotein nitrogen fell to 24 mg. per hundred cubic centimeters from 30, and the serum sugar continued to remain the same. The serum volume had risen to 3.3 liters from 2.3 liters at the start of the administration of desoxycorticosterone. The extracellular fluid volume had risen from 15.9 at the start to 28.3 liters. The blood pressure remained about the same. The serum cholesterol had fallen to 89 mg. per hundred cubic centimeters from 102. The restriction of salt and water for three days was necessary to stop progressive gain in edema and cardiac insufficiency. Thereafter the patient was on an unlimited diet and fluid intake. Salt was restricted somewhat and he was given 5 mg. of desoxycorticosterone every two to three days. He gradually lost his edema, his venous pressure and vital capacity returned to normal, his cardiac dilatation disappeared (fig. 6) and about six weeks after the first injection of desoxycorticosterone he had gained 14 Kg. and had no edema. His serum sodium remained about 135.5 milliequivalents per liter, potassium 4 milliequivalents per liter, the serum protein had risen to 6.6 per hundred cubic centimeters and the serum cholesterol to 134 mg. per hundred cubic centimeters. The extracellular fluid volume was 25.5 liters and the blood volume 4.6 liters as against 28.3 and 4.5 liters respectively at the height of his edema. At this time his blood pressure had risen about 15 mm. of mercury systolic but the diastolic had not changed and he still had a blood pressure consistently under 100. His general clinical status was as different from his original condition as possible and he felt perfectly well up and around. He was given a constant diet again for a six day period and given 25 mg. of desoxycorticosterone by mouth for three days. This was five times the amount needed to maintain him when given subcutaneously and had no effect on his chloride excretion or on his serum values. He lost weight and the serum potassium rose from 4.4 to 5.4 milliequivalents per liter on this regimen. He was returned to his former regimen of desoxycorticosterone 5 mg.

every two to three days and a regular diet with no added salt and had the fistula in ano repaired. He was under general anesthesia for an hour and withstood the operation uneventfully with only one saline infusion postoperatively. He is now still in the hospital, recovering from his operation, and two and one-half months after the start of desoxycorticosterone administration he has gained a total of 14 Kg. and has maintained his serum electrolyte values at nearly normal levels on 5 mg. of desoxycorticosterone every three days. More than this leads to edema. His blood pressure after ten weeks of desoxycorticosterone remains below 100. A dextrose tolerance curve done two months after the start showed a flat curve but no hypoglycemia four hours after ingestion of 100 Gm. of dextrose.

CASE 4.—History.—F. D., a man aged 41, married, an editor, had a nervous breakdown in 1920 and progressive leukoderma since 1921. In 1936 he noticed that his summer tan did not fade in the winter. Beginning in August 1937 he suffered from increasing weakness, anorexia and loss of weight (20 pounds, 9 Kg.) in all. On admission his blood pressure was 70 systolic, 60 diastolic, and his nonleukodermic skin was pigmented but there was no pigmentation of the mucous membranes. The blood count and urine were normal; the sedimentation rate was 20 mm. in one hour. Roentgenograms of the chest and adrenal areas were negative. The serum sodium was 127.7 milliequivalents per liter, potassium 5.6 milliequivalents per liter, the blood sugar 96 mg. per hundred cubic centimeters and the nonprotein nitrogen 47 mg. per hundred cubic centimeters.

On salt administration he improved greatly and the addition of cortical extract made little if any difference. He was followed in the hospital and clinic until Jan. 5, 1939, when he was readmitted for desoxycorticosterone administration. During this time he was able to work at intervals, his serum sodium remaining normal most of the time but his blood pressure usually being below 100 systolic.

Fig. 4 (case 5).—Comparison of effects of progesterone and desoxycorticosterone propionate.

A man of 40 with Addison's disease greatly helped by salt administration but never returning to normal strength, his emotional make-up interfered with an accurate appraisal of his condition at times. There was no evidence of tuberculosis. Leukoderma was a coexisting condition.

Treatment with Desoxycorticosterone.—The patient was placed on a constant diet containing known amounts of sodium chloride (11.6 Gm.), potassium and water. He was then given 25 mg. of desoxycorticosterone intramuscularly daily for four days and gained 1 Kg. in weight. The urine volume was decreased by

about 10 per cent, the urine chloride by 50 per cent, the urine sodium by 70 per cent. The urine nitrogen was increased by about 10 per cent and the potassium by about 50 per cent. The serum sodium rose from 136.3 to 141.6 milliequivalents per liter, chloride from 100 to 104.8 milliequivalents per liter, bicarbonate from 26.3 to 26.7 milliequivalents per liter. The serum potassium was decreased from 5.2 to 4.4 milliequivalents per liter, the protein from 7.1 to 5.9 per cent, the cholesterol from 279 to 192 mg. per hundred cubic centimeters, the nonprotein

Fig. 5 (case 3).—Pulmonary congestion and dilatation of the right side of the heart associated with a gain of 11 Kg. during ten days' treatment with desoxycorticosterone propionate.

Fig. 6 (case 3).—Disappearance of pulmonary congestion and dilatation of the heart two weeks after the cessation of desoxycorticosterone propionate injections and the limitation of salt and water in the diet.

nitrogen and sugar remained about the same and the hematocrit reading fell from 44.5 per cent to 37 per cent cells. Desoxycorticosterone was continued for six more days, from 10 to 15 mg. daily, and he gained another kilogram and had no rise in blood pressure. The urine volume remained about 10 per cent less than in the foreperiod, the nitrogen was 10 per cent less than in the foreperiod, the chloride was about 50 per cent of that of the foreperiod, the sodium about 50 per cent and the potassium excretion was increased about 25 per cent. The serum sodium continued elevated at 143.2, chloride at 108.8 milliequivalents per liter, bicarbonate at 27 milliequivalents per liter, nonprotein nitrogen fell from 32 to 21 mg. per hundred cubic centimeters and serum potassium, protein and sugar did not change during this additional six days on desoxycorticosterone. For the whole ten day period the extracellular fluid volume rose 2.3 liters and serum volume rose 800 cc. The hematocrit reading fell from 44.5 to 34 per cent cells. He was discharged to the clinic on 12.5 mg. of desoxycorticosterone given subcutaneously by himself daily with between 5 and 10 Gm. of sodium chloride added to the diet and has continued to gain weight. When last seen, two months after the start of desoxycorticosterone administration, he was feeling well, was gainfully employed and was maintaining a blood pressure of 120 systolic, 85 diastolic as well as a serum sodium of 140 and a potassium of 3.9 milliequivalents per liter. He never developed any peripheral edema but at times noted that his face was puffy.

CASE 11.—History.—R. F., a man aged 33, married, an elevator operator, began to notice weakness, anorexia and loss of weight (60 pounds, 27 Kg., in all) in the fall of 1937. Over about the same period "brown spots" appeared on his skin. Following tonsillectomy on May 21, 1938, he began to have nausea and vomiting and was admitted to Bellevue Hospital, where he remained three and one-half months with the diagnosis of Addison's disease. The serum sodium at this time was 115.9 milliequivalents per liter. He responded well to sodium chloride but implantation of an adrenal gland into the right rectus was ineffective.

Sept. 12, 1938, he began visiting the Vanderbilt Clinic. He presented the classic picture of weakness, pigmentation of the skin and mucous membranes and a blood pressure of 95 systolic, 70 diastolic. He had a mild secondary anemia, x-ray examination of his chest showed healed tuberculosis at the left apex, and his adrenal areas contained shadows of calcium density. The serum sodium was 141 milliequivalents per liter, potassium 4.5 milliequivalents per liter, sugar 83 mg. per hundred cubic centimeters and nonprotein nitrogen 22 mg. per hundred cubic centimeters. On approximately 15 Gm. of sodium chloride and a low potassium diet he improved greatly.

Jan. 2, 1939, he was admitted to the Presbyterian Hospital acutely ill with hemolytic streptococcus sore throat. The serum sodium was 132 milliequivalents per liter. Again on February 20 he came into the hospital with fever. This lasted for more than a week and was never satisfactorily explained. Roentgenograms of the spine showed a destruction of the intervertebral disks between the fourth and fifth dorsal vertebrae suggesting tuberculosis, probably inactive. He was discharged March 11 with a relatively normal temperature, a blood pressure of 90/60, sedimentation rate 78 mm. in one hour and a calculated serum sodium of 137 milliequivalents per liter. He returned to the Vanderbilt Clinic for Doca administration April 3.

A man of 33, with classic Addison's disease due to tuberculosis, he survived two febrile episodes by the use of sodium chloride. He had inactive pulmonary and spinal tuberculosis.

Treatment with Desoxycorticosterone.—The patient was treated in the clinic. He was on his usual diet at home with from two to three teaspoonfuls of salt added to the diet. During the first week of the administration of desoxycorticosterone (15 mg. every two days) he gained 1.5 Kg. in weight and his blood pressure rose from 95/70 to 120/75. Serum chloride showed no change, his serum protein fell from 7.0 to 6.8 per cent, and his blood sugar remained constant at 65 to 75 mg. per hundred cubic centimeters. He was taught to inject the desoxycorticosterone himself at home and after seven weeks of 15 mg.

Fig. 7 (case 11).—Appearance of heart before treatment with desoxycorticosterone acetate.

Fig. 8 (case 11).—Appearance of heart after treatment with desoxycorticosterone acetate.

every other day he gained 2.6 Kg. and maintained his blood pressure at the normal level of 120/80. His serum protein had fallen to 6.4 per cent, nonprotein nitrogen from 27 to 22 mg. per hundred cubic centimeters and serum chloride remained the same, about 106 milliequivalents per liter. He felt much improved, developed a large appetite, and although he stated that his ankles had been swollen at night, this edema had never been observed in the clinic in the morning. Three weeks after his last clinic visit and approximately two months after he had begun to take desoxycorticosterone he was admitted to the ward

with a story of slowly increasing dyspnea for three weeks, severe enough in the past two weeks to confine him to his fifth floor room. This was accompanied by nonradiating squeezing, substernal pain. Two days before admission he had complained of nausea, vomiting and epigastric cramps. On examination he was dyspneic with slight cyanosis, and his face was puffy. Fine rales and dullness were present at the right base. The pulmonic second sound was greater than the aortic second sound. A tender liver was felt two fingerbreadths below the costal margin. There was no pitting edema. The temperature was 99.4, blood pressure 130/100, vital capacity 1,300 cc., venous pressure 140 mm. of water, rising to 200 following an infusion of 200 cc. of physiologic solution of sodium chloride. The circulation time was 64 seconds (calcium gluconate), serum sodium was 143.5 milliequivalents per liter, potassium 3.2 milliequivalents per liter, protein 6 per cent, sugar 80 mg. per hundred cubic centimeters. X-ray examination of the heart (fig. 8) showed marked increase in size both to the right and to the left, contrasting sharply with a normal cardiac contour shown on a roentgenogram taken four months earlier (fig. 7). An electrocardiogram showed little beyond the voltage lower than that of the record taken four months previously. The urine contained 3 plus albumin and no significant cells. Desoxycorticosterone and salt were withheld. On the day following admission, his blood pressure rose to 150/130 and because of increasing dyspnea and cyanosis together with a venous pressure of 250 mm. of water, he was digitalized parenterally, 400 cc. of blood was withdrawn by phlebotomy, and he was put in an oxygen tent. The following morning his temperature had risen to 103 F., venous pressure had fallen to 100 mm. of water and throughout the day his blood pressure fell from 130/80 to 60/40, responding only briefly to an infusion of 1,250 cc. of 5 per cent dextrose in saline solution. The heart sounds became poor, his pulse became irregular and he died the following morning after ten hours of coma with increasing tachypnea and irregular tachycardia. Postmortem examination revealed no gross cause for cardiac failure, although there was slight cardiac hypertrophy and marked dilatation. Only about 150 cc. of fluid was present in the pericardium, and a mild bronchopneumonia was also present. There was also advanced tuberculosis of both adrenal glands.

SUMMARY

1. The use of desoxycorticosterone esters in patients with Addison's disease produces striking clinical and physiologic effects.
2. Clinically there is unequivocal improvement far greater than has resulted from any therapy hitherto advocated.
3. The most striking physiologic effects are on salt and water metabolism. The administration of desoxycorticosterone esters causes retention of sodium and water. The result of this retention is an improvement in the patient's condition which is qualitatively identical with that following the administration of salt and water alone, but quantitatively it is far more marked.
4. No effect on carbohydrate metabolism has been observed.
5. Patients vary greatly in the amounts of desoxycorticosterone esters required to alleviate the manifestations of adrenal insufficiency.
6. Extreme caution must be exercised in the administration of desoxycorticosterone esters because excessive amounts may lead to the development of hypoproteinemia, marked edema and cardiac insufficiency.

ADDENDUM.—Since this article was written, it has been found that patients do most satisfactorily with small daily doses of synthetic hormone without the addition of salt beyond that of the usual diet. It may also be pointed out that patient 7 developed transient dilatation of the heart, relieved by the withdrawal of salt. Furthermore, patient 5 died suddenly at home while under treatment while the blood pressure was normal and without fever.

Clinical Notes, Suggestions and New Instruments

A DEVICE FOR TURNING THE FRAME PATIENT

HOMER STRYKER, M.D., ANN ARBOR, MICH.

Hospitals or physicians who use the anterior and posterior Bradford frames are confronted with the nursing problem of changing the patient from one frame to the other. A method which enables one nurse to turn any patient without lifting and with a minimum of discomfort to the patient is herein

Fig. 1.—Patient on posterior Bradford frame with foot and arm supports attached. The frame is supported by the turning devices attached to the ends of the bed. These also support the overhead frame, from which is suspended a small cabinet the door of which serves as a reading board or, when lowered, a writing board.

described. It has been found satisfactory in the daily care of from fifteen to twenty such patients at the University Hospital. If a patient who requires frame care is allowed to remain a part of the day on his abdomen, he is more comfortable and is less liable to develop decubital ulcers or respiratory or renal complications.

Fig. 2.—The nurse has removed the cabinet and the arm and foot supports and is placing the anterior frame down over the patient, where it is fastened by a wing nut at each end.

METHOD OF TURNING PATIENT

The patient is placed on his back on a posterior frame. This frame is then suspended about 1 foot from the mattress, each end being attached to a turning device which clamps on to the

From the Orthopedic Service of Dr. Carl E. Badgley.
From the Department of Surgery, University of Michigan Medical School.

head and foot of the bed. To turn the patient, the anterior frame is placed over him and pressed down firmly, pressing him between the two frames. The anterior frame is then locked in this position. The nurse then releases a spring lock at the end and revolves the two frames, with the patient between them, through an angle of 180 degrees, whereupon the frames automatically lock again, leaving the patient face downward on

Fig. 3.—The nurse has released the lock and is turning the frames with the patient compressed between them. When face downward the frames automatically lock and the posterior frame is then released and lifted off. The face support and rubber bands which hold the canvas taut are shown in this view.

the anterior frame. Since the patient simply revolves on his long axis without change of the center of gravity, little effort is required for the turning. The upper frame (posterior) is now released and lifted off.

While on the anterior frame, the head is supported by an adjustable face piece which lies on the anterior frame and takes the weight on the cheeks and forehead. It is padded with sponge rubber and has flannel covers which may be removed

Fig. 4.—Patient on anterior frame. This is the portable unit in which the turning devices, instead of clamping on the bed ends, are supported by a base which sets on the bed. It may be transported as a unit and rests on any level surface.

for washing. The eyes are about 15 inches from the mattress, a comfortable distance for reading and writing. The anterior frame is narrowed at the shoulders to allow the arms to be brought down over the sides for comfort. In some cases frequent turning may be required, but usually the patient remains on the anterior frame during the day. At night the patient is turned in the same manner to the posterior frame.

TYPE OF FRAMES

By means of turn buckles at each end, the adult frames are adjustable in width between 12 and 17 inches, children's from

7 to 12 inches. No patient requires a frame more than 17 inches in width—over this it becomes a hammock and no longer effectively supports the spine.

Our frames are made of light weight tubing but gas pipe frames of proper length may be used with the turners by drilling a five-eighths inch hole in the center of each end by which they are fastened to the turning disk. For a standard bed they should be 6 feet 3 inches long and for the portable unit they are 6 feet 1 inch long.

COVERING OF FRAMES

The frames are covered with heavy canvas, with eyelets at 4 inch intervals along each side, and wide enough to fold over the sides of the frame when set at its greatest width. Bands of rubber stretched across the back between the eyelets are used in place of laces or straps with buckles. This keeps the canvas perpetually and evenly taut, provides for personal variations in contour and allows changing the width of the frame without removal of the frame covers. They are easily applied or removed and eliminate the necessity of frequent adjustment. A spreader is placed beneath the center of each frame to maintain uniform width. The canvas is padded with celotex or 1 inch sponge rubber, over which a draw sheet is placed and pinned beneath the frame. A 6 inch opening at the center allows toilet service. The small (6 inch diameter) chamber

Fig. 5.—Patient on portable unit being transported to ambulance. The overhead frame, anterior frame and accessories have been detached for transportation.

mug commonly used for infants will be found more satisfactory than the conventional bedpan. It can be lifted up through the opening overlapping the edge of the canvas, which prevents soiling.

SUPPORTS FOR ARMS AND FEET

Attachments are provided for the support of the feet at right angles and for the arms at the sides of the frame. These are easily applied or removed while the patient is on the frame. The arm supports may also be used to hold the tray at mealtime.

TYPE OF BED

The turners fit on the head and foot of any standard hospital bed of either round or square design. A socket is provided on top of each turning device for the insertion of an overhead frame if desired. The turners may be used for this purpose with or without the Bradford frames. A cabinet with a reading board may be suspended from the overhead frame.

PORTABLE UNIT

For those patients who require a continuation of frame care at home or elsewhere, a portable unit is provided in which the turning device is fastened to a base which sets on the bed at the hospital or at home and may be transferred with the patient as a unit in an ambulance or invalid car. This has been especially appreciated when there is only one person available in the home to care for the patient.

1101 Baldwin Avenue.

THREE FATAL CASES OF SODIUM NITRITE
POISONING

LOUIS R. PADBERG, M.D., AND THOMAS MARTIN, M.D.
Coroner and Autopsy Physician, Respectively
St. Louis

Sodium nitrite and other inorganic nitrites are used mainly in the manufacture of dyestuffs and more recently as anti-corrosives in automobile anti-freeze mixtures. Inorganic nitrites are rarely encountered as the cause of human poisoning. It is therefore considered of value to report the following cases:

Three white men, J. N., aged 55, T. H., aged 65, and A. K., aged 70, were inmates of a cheap lodging house near the river front, the location of several wholesale chemical companies, one of which is a large distributor of sodium nitrite. Oct. 27, 1938, at about noon these three men were observed preparing a meal consisting of "beef stew" in the room of J. N. Four hours later the landlady of the house saw A. K. staggering down the stairs; when he reached the bottom he collapsed without making a statement. The landlady stated that the man's face was very pale and that his lips and the areas around the lips were purplish. The City Hospital ambulance was called, and all three men were pronounced dead on arrival at the hospital.

The bodies were immediately taken to the city morgue, where autopsies were performed.

SUMMARY OF AUTOPSIES

Gross examination of the three bodies showed the following conditions in each body:

The skin was very cyanotic, about the color of slate; the blood was thin and did not coagulate and was a dark brown, simulating prune juice.

Specifically the results of the examination in each are recorded as follows:

J. N. was 5 feet 8 inches (173 cm.) tall and weighed 140 pounds (63.5 Kg.). The hair was white and the eyes were blue; the left forearm had been amputated below the elbow. Dense fibrotic adhesions were seen in the right pleural cavity and old fibrosis was present throughout the right lung, particularly in the apex. The capsule of the kidney was adherent and did not strip readily. Other than this there were no gross abnormalities.

T. H. was 5 feet 11 inches (180 cm.) tall and weighed 175 pounds (79.4 Kg.). The hair was white and the eyes were blue. There was edema of the brain and lungs, hypertrophy of the heart, moderate sclerosis of the vessels and degenerative changes within the kidney.

A. K. was 5 feet 10 inches (178 cm.) tall and weighed 180 pounds (81.6 Kg.). The hair was white and the eyes were blue. There was edema of the brain and lungs, hypertrophy of the heart with atheromatous changes in the aorta and sclerosis of the coronary. The arteries were moderately sclerosed and the kidney showed some parenchymatous changes. Other than these abnormalities the gross examination of all viscera except the stomach was negative.

The three deaths occurring almost simultaneously after a meal might have been suggestive of botulism except that the time factor was too short and the food eaten was known to have been cooked. The viscera and blood samples of the three men together with a portion of the "stew," a box of salt and pepper and an ice cream carton containing a yellowish white crystalline substance were submitted to the coroner's toxicologist for chemical examination. Within forty-eight hours the following report was received:

On acid steam distillation of 100 Gm. portions of each portion of stomach and contents there was chemically detected in the dilute sodium hydroxide of the receiver the presence of a nitrite. A portion of this nitrite was subsequently isolated as silver nitrite and so identified. A quantitative analysis was performed on steam distillates from weighed portions of stomach and contents by the method of Lunge. Approximate amounts of nitrite, calculated as sodium nitrite and based on total weights of stomach and contents, are as follows: in J. N., 0.5 Gm. of sodium nitrite; in T. H., 0.7 Gm., and in A. K., 0.1 Gm.

Samples of the blood of the three men were submitted to spectroscopic examination for the presence of methemoglobin:

A strong absorption band of methemoglobin (630) was observed at 1:100 dilution, μ_n 7.1, in all three samples.

A portion of food containing meat and tomatoes was submitted to acid steam distillation and the presence of a nitrite was detected in the distillate.

The sample of salt and pepper was examined and found to be sodium chloride and finely ground black pepper.

Seventy-five Gm. of a yellowish white crystalline substance contained in an ice cream carton was submitted to analysis and found to be almost chemically pure sodium nitrite.

A thorough investigation was made as to the motive, but up to the present time these cases are unsolved, i.e. as to whether they were accidental, suicidal or homicidal.

1300 Clark Avenue.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORTS. HOWARD A. CARTER, SECRETARY.

POLYTHERM SHORT WAVE APPARATUS ACCEPTABLE

Manufacturer: Polytherm, Incorporated, 707 Broadway, Paterson, N. J.

The Polytherm Short Wave Apparatus considered in this report includes the "Advance," "Standard Cabinet" and "Portable" models. These units are identical in circuit and component parts. They are designed for use in medical and minor surgical diathermy. Standard equipment includes pad electrodes, felt spacers and surgical accessories.

Two tubes (211-B) are employed in a typical tuned-plate, tuned-grid circuit, operating at approximately 14 meters wavelength. There is a ventilator to dissipate heat from the tubes by convection. The bipolar surgery which is optional on any unit is the introduction of one terminal which is a tap on the output or pick-up coil.

The Council tests showed that with an input of 610 watts and an electromotive force of 120 volts, the maximum output obtainable was 245 watts. After two hours of operation at a maximum input of 610 watts the Council tests demonstrated a final temperature in the outside windings of the transformer which stayed within allowable limits.

The firm submitted evidence to substantiate the efficacy of the machine in producing a temperature rise in the human thigh

Polytherm Short
Wave Apparatus.

Diagram of circuit.

with the cuff technic. A reliable investigator was secured by the firm to perform these tests. Six tests were carried out and three normal male subjects were used. Cuffs measuring $17\frac{3}{4}$ by $4\frac{3}{4}$ inches were wrapped about the thigh, $7\frac{1}{2}$ inches apart. The average spacing was $1\frac{1}{4}$ inches for the right and $1\frac{1}{4}$ inches for the left. Temperature measurements were taken by thermocouples before and after twenty minute treatments. The thermocouples were inserted into the subcutaneous and intramuscular

tissue in the usual manner. Rectal temperatures were observed. The average room temperature was 76 F. The room humidity was 72 per cent.

Average temperatures (F.) of six observations after applying heat for twenty minutes are given in the accompanying table.

Average Temperatures of Six Observations

Deep Muscle		Rectal	
Initial	Final	Initial	Final
97.9	107.2	99.5	99.6

The unit was investigated clinically by the Council and found to give satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Polytherm Short Wave Apparatus, "Advance," "Standard Cabinet" and "Portable" Models, for inclusion in its list of accepted devices for use with the cuff technic.

TROPIDORES ACCEPTABLE

Manufacturer: Hill Laboratories Company, 128 Lancaster Avenue, Wayne, Pa.

The Tropidores is a device for continuous, local, heated air therapy. The system consists of the moving of warm air through flexible garments that may be applied locally and worn for as long as desired on the affected parts of the body. The unit is portable, the machine being small enough to be put on an ordinary bedside table. The complete assembly consists of (1) the motor, intake fan and heating coil chamber, (2) master conveying tube and connecting tubes, (3) two boots for the legs (hip length), (4) one sleeve and (5) jacket for the treatment of thorax and torso regions, supplied separately and made up according to specifications.

Tropidores.

The manufacturer states that the Tropidores is designed to induce heat controllable at any desired degree up to 145 F., which temperature is claimed to be safe when constantly applied on the full length of the extremities without danger of shock or evidence of rise of temperature in the mouth. Heated air by means of a fan with a capacity of 30 cubic feet per minute is blown through a tube. The total consumption of electricity when a standard coil is used is 230 watts an hour. The apparatus may be attached to an ordinary electric light socket by a 12 foot cable and will be supplied for alternating or direct current as specified.

The large hose from the machine is fitted into a three way connection leading to smaller hose and to the vestibules, which are at one end of each garment and allow the passage of air into the garments through numerous holes. All vestibules are removable to permit sterilization. The garments are of canvas and supplied with flannel trimmings at all body contact points, slide fasteners and draw strings. They are supposed to provide freedom of arm and leg movement and to allow the patient to turn in bed without readjusting the apparatus. The hose are also flexible. Heavy woolen stockings and gloves should be worn under Tropidores garments for the purpose of absorbing perspiration, which acts as a humidifier of inducted air. Slide fasteners should be left partly open to permit a constant flow of air.

An investigation of the unit was conducted by the Council, from which study it appeared probable that the Tropidores offers a convenient form of heated air therapy for those who are bedfast. It is necessary that an attendant, trained in the use of this apparatus, supervise the treatments, because it is possible to create unduly heated areas close to the entrance of the heated air into the garment. If the treatments are of long duration, caution must be exercised lest the sweating be so

prolonged as to cause weakness. Some restlessness and fatigue also were shown by those who were treated over four hours. It was found further, as might be expected, that there was a drop of temperature of about 15 or 20 F. from the original before the air reached the joints of the extremities.

In the light of the foregoing report, the Council on Physical Therapy voted to include the Tropidores in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

DILANTIN SODIUM

Sodium 5, 5-diphenyl hydantoinate, originally presented to the Council under the name "Dilantin" and marketed as "Kapseals Dilantin" by Parke, Davis & Company, has been redesignated "Dilantin Sodium" and is now marketed as "Kapseals Dilantin Sodium." Dilantin Sodium is an active anticonvulsant and relatively feeble hypnotic, used in the treatment of epilepsy. H. H. Merritt and Trace J. Putnam studied the anticonvulsant action of a number of drugs, including Dilantin Sodium,¹ and later they reported² the results of the treatment of 150 epileptic

* The Council's referee accepted this figure without verifying it.

† Dilantin plus bromides.

patients with this drug. The Council also received a report of the treatment of fifty-two epileptic children by Dr. O. P. Kimball of Cleveland. While these clinical studies pointed to the therapeutic value of Dilantin Sodium the Council requested additional information, with especial reference to the toxicology, the side actions and the limitations of its usefulness.

Pharmacologic studies were conducted in the laboratories of Parke, Davis and Company, and clinical investigations were made in a number of institutions, five of them in institutions for the treatment of epilepsy and kindred conditions.

The pharmacologic studies show that Dilantin Sodium is of relatively low toxicity when administered orally to rats, rabbits and dogs, and much more toxic when injected intravenously. A special investigation was conducted to show whether Dilantin Sodium interferes with the utilization of ascorbic acid, after Kimball had reported hyperplasia of the gums suggestive of

1. Merritt, H. H., and Putnam, T. J.: A New Series of Anticonvulsant Drugs Tested by Experiments on Animals, *Arch. Neurol. & Psychiat.* 39: 1003 (May) 1938.

2. Merritt, H. H., and Putnam, T. J.: Sodium Diphenyl Hydantoinate in the Treatment of Convulsive Disorders, *J. A. M. A.* 111: 1065 (Sept. 17) 1938.

scurvy. The results of the experiments on animals did not indicate that the drug has any influence on the utilization of ascorbic acid.

Physicians who studied Dilantin Sodium therapeutically were furnished with forms for recording data. Some sixty pages of these forms were submitted to the Council by the firm, which received them from ten observers who had treated 437 patients. The headings of the forms included history, age, sex, age at onset, etiology, type of attacks, reactions and treatment, including dosages and a comparison of results with phenobarbital and Dilantin Sodium.

The side actions reported by one or more include dizziness, dry skin, dermatitis, rash, itching, tremors, fever with temperature of 104 F. in one case, nausea, vomiting, blurred vision, fatigue, apathy, difficult breathing and swallowing, nervousness, mental confusion and active hallucinations. Hyperplasia of the gums has been reported by Kimball.

It would require much space to present a summary of the work of every one of the clinical investigators, but it is believed that the accompanying table submitted by Parke, Davis and Company (and confirmed by the Council's referee) affords a fair statement of the chief points of interest.

The Council voted that the firm be informed (1) that the available evidence justifies the recognition of Dilantin Sodium as a therapeutic agent of promising value in the treatment of many cases of epilepsy and (2) that Dilantin Sodium will be accepted for inclusion in N. N. R. provided the firm will agree to market it under rigid restrictions, including those which further experience shall indicate, as well as the following: (a) It shall not be recommended for use by the general practitioner unless he is able to maintain a close (daily) supervision of the patient, until the scope of its usefulness as well as its side actions have been determined more accurately; (b) it is not to be recommended for the treatment of those patients whose seizures occur only at long intervals unless moderate doses of phenobarbital are ineffective or induce disagreeable side actions. The firm has agreed to these conditions. The A. M. A. Chemical Laboratory has found the composition of Dilantin Sodium satisfactory.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

DILANTIN SODIUM.—Sodium 5,5-diphenyl-hydantoinate. — Sodium 2,4-diketo-5,5-diphenyl-tetrahydroglyoxaline. — The mono-sodium salt of 5,5-diphenyl-hydantoin,

$\text{Na}(\text{C}_6\text{H}_5)_2\text{C.NH.CO:N.C:O}.$

Actions and Uses.—Dilantin sodium is an anticonvulsant with a relatively weak hypnotic action. It is used in the treatment of epileptic patients who are not benefited by phenobarbital or bromides and those in whom these drugs induce disagreeable side actions. Dilantin sodium appears to be more effective in controlling seizures of the grand mal type than in those of the petit mal. It does not cure congenital mental defects or the mental deterioration often observed in the epileptic. Various side actions of different degrees of severity which have been observed include dizziness, dry skin, dermatitis, rash, itching, tremors, fever, nausea, vomiting, blurred vision, fatigue, apathy, difficult breathing and swallowing, nervousness, mental confusion and active hallucinations, and hyperplasia of the gums suggestive of scurvy, though its use does not interfere with the utilization of vitamin C. Dilantin sodium is strongly alkaline and it may give rise to gastric irritation.

Dosage.—The optimum dosage of dilantin sodium must be determined by the daily observation of its effects by the physician. The influence of the drug on seizures and the appearance of any of the side actions enumerated must be a guide to the dosage. Mild symptoms do not necessarily require that the dosage be stopped. The beginning adult dose is 0.1 Gm. (1½ grains) with at least half a glass of water three times daily. If necessary this dose may be increased gradually to 0.2 Gm. (3 grains) three times daily. Children above the age of 6 years may be given 0.1 Gm. (1½ grains) three times daily for one

week, after which it may be increased if necessary to 0.1 Gm. (1½ grains) four times daily with at least half a glass of water to prevent gastric irritation due to the alkalinity. Dilantin sodium is more rapidly effective if given before meals, but should it cause gastric irritation it should be given immediately after meals. Children under 4 years of age may start with 0.03 Gm. (one-half grain) mixed with cream (to disguise the bitter taste and to prevent gastric irritation) twice a day. Obviously such doses require the most careful supervision. If this dose is borne without side actions the dosage may be increased to 0.03 Gm. (one-half grain) three or four times a day. Every slight increase in dosage is made only after the physician is convinced that such increase is necessary and that no harm is to be anticipated.

The transition from phenobarbital, bromides or other hypnotic-type drugs to dilantin sodium should be made gradually with some overlapping in dosage. By this procedure the danger of phenobarbital or bromide withdrawal symptoms (increased number of seizures) is minimized, and side actions incident to the beginning administration of Dilantin Sodium are lessened.

Manufactured by Parke, Davis & Co., Detroit. No U. S. patent. U. S. trademark applied for.

Kapsals Dilantin Sodium 0.1 Gm. (1½ grains): Each kapsal (hermetically sealed capsule) contains 0.1 Gm. (1½ grains) of sodium 5,5-diphenyl hydantoinate.

Kapsals Dilantin Sodium 0.03 Gm. (½ grain): Each kapsal (hermetically sealed capsule) contains 0.03 Gm. (½ grain) of sodium 5,5-diphenyl hydantoinate.

Dilantin sodium occurs as an odorless, white, microcrystalline powder, possessing a slightly bitter taste. It is soluble in alcohol and glacial acetic acid; practically insoluble in ether, petroleum ether and benzene. Aqueous solutions of dilantin sodium yield an opalescent crystalline precipitate of diphenyl-hydantoin, which dissolves when the pH of the mixture is adjusted to 11.7.

Dissolve about 0.25 Gm. of dilantin sodium in 5 cc. of boiled water; the mixture should not require more than 1 cc. of tenth-normal alkali to produce a clear, colorless solution; add an excess of diluted hydrochloric acid, shake thoroughly, collect the precipitated diphenyl-hydantoin on a filter paper, wash with water and dry at 95 C.; it melts at 293-299 C. with decomposition.

Treat about 0.5 Gm. of dilantin sodium with 10 cc. of solution of sodium hypochlorite, heat to 50 C., pass in carbon dioxide; collect the precipitate formed on a filter paper. Dry the precipitate in a partial vacuum and recrystallize from chloroform; the melting point of the 5,5-diphenyl-1,3-dichloro-hydantoin lies between 163 and 167 C.

Incinerate about 0.2 Gm. of dilantin sodium; the residue responds to tests for sodium carbonate.

Dissolve about 0.5 Gm. of dilantin sodium in 100 cc. of water, add 5 cc. of diluted nitric acid, shake and filter through paper; separate portions of 10 cc. each of the filtrate yield no greater opalescence on addition of 1 cc. of silver nitrate solution than that produced by 0.25 cc. of tenth normal hydrochloric acid in 50 cc. of water (chlorides) or no appreciable turbidity on the addition of 1 cc. of barium nitrate solution (sulfates). Acidify about 0.2 Gm. of dilantin sodium in 50 cc. of water with diluted hydrochloric acid, using litmus paper as the indicator; filter through paper; a 10 cc. portion of the filtrate yields no color or precipitate on saturating with hydrogen sulfide (salts of heavy metals). Dissolve 0.1 Gm. of dilantin sodium in 5 cc. of sulfuric acid; the color produced should not be greater than that yielded by 0.1 mg. of benzoic acid in 5 cc. of sulfuric acid.

Heat about 0.5 Gm. of dilantin sodium, accurately weighed, to constant weight at 95 C.; the loss in weight should not exceed 2.5 per cent. Transfer about 0.25 Gm. of the dry dilantin sodium, accurately weighed, to a separatory funnel, add 50 cc. of water and 10 cc. of diluted hydrochloric acid; extract the mixture with 100 cc. of ether and repeat the extraction with four successive 25 cc. portions of ether; evaporate the combined ether extracts in a tared beaker and dry to constant weight at 95 C.; the 5,5-diphenyl-hydantoin should amount to not less than 90.6 per cent, nor more than 92.0 per cent of the dry sample, and should melt above 292 C.

FUNGUS EXTRACTS-ABBOTT.—Liquids obtained by extracting dried spores with a menstruum consisting of equal volumes of glycerin and a solution containing sodium chloride 5 Gm. and sodium bicarbonate 2.7 Gm. in distilled water 1,000 cc.

Actions and Uses.—See general article Allergic Protein Preparations, New and Nonofficial Remedies, 1939, p. 27.

Dosage.—See general article Allergic Protein Preparations, New and Nonofficial Remedies, 1939, p. 27.

Fungus Extracts-Abbott are marketed in 2 cc., 5 cc. and 30 cc. vials.

Manufactured by the Abbott Laboratories, North Chicago, Ill. No U. S. patent or trademark.

Alternaria spp. Fungus Extract-Abbott: *Aspergillus fumigatus* Fungus Extract-Abbott; *Aspergillus niger* Group Fungus Extract-Abbott; *Cephalothecium roseum* Fungus Extract-Abbott; *Hormodendrum* spp. Fungus Extract-Abbott; *Monilia sitophila* Fungus Extract-Abbott; *Mucor* spp. Fungus Extract-Abbott; *Penicillium rubrum* Fungus Extract-Abbott; *Ustilago zeae* (Corn Smut) Fungus Extract-Abbott; *Yeast* Fungus Extract-Abbott.

The yeast extract is prepared from dried brewers' yeast; the *Alternaria* spp. extract is prepared from the dried mass of spores with its supporting mycelium; the other extracts are prepared from the dried spores alone. The material is extracted at room temperature with a menstruum consisting of equal volumes of glycerin and a solution containing sodium chloride 5 Gm. and sodium bicarbonate 2.7 Gm. in distilled water 1,000 cc. for from four to five days and is clarified and sterilized by Berkefeld filtration. The finished liquid is a 5% W/V 0.05 Gm. of dried fungus material, each cubic centimeter representing

MEDICAL SERVICE IN A TEACHING HOSPITAL—DR. CHRISTIAN'S "FAREWELL REPORT"

Medicine has developed through the labor of many and under the leadership of relatively few. During the past half century medicine in general, and American medicine in particular, have undergone revolutionary changes. The mystic, religious and philosophical domination has given way to the influence of natural and social sciences. The beneficial yield of objectivity to human society has surpassed the most optimistic expectations. Will the importance of personal leadership wane in the light of these recent changes? A superficial analysis of this problem might suggest that the introduction of exact sciences into medicine has decreased considerably the need for leadership. A more detailed study of the question indicates however that, precisely because of the rapid growth and of the diversified interests represented in modern medicine, guidance and correlation in medical education and practice are becoming more important than ever.

The Peter Bent Brigham Hospital under the leadership of Dr. Henry A. Christian and the late Dr. Harvey Cushing assumed a significant role in the establishment of modern clinical medicine in America. When the doors of this university clinic opened in 1913, it was one of the few institutions in the country which especially cultivated scientific clinical medicine. Since then fortunately the situation has changed. Now there are a number of important medical centers which represent different experiments in medical education. For this reason Dr. Christian's "farewell report" in the twenty-fifth Annual Report of the Peter Bent Brigham Hospital is of particular interest.¹ Here is the advice of a physician in chief who during a quarter of a century observed intimately the development of American medicine.

Dr. Christian describes what he believes should be the aims and the spirit of a medical service in a hospital. He points out that he who directs a hospital

service must have a plan, a method, an ideal of perfection. The service must represent the highest accomplishment of leadership. Time and conditions change rapidly. Hence always there must be a willingness to meet changing conditions. A spirit of friendly helpfulness should pervade both the practical care of the patient and the scientific study of the medical problem. The best possible professional care should be administered to the patient in such a way that he feels that all in the hospital are interested in him as an individual. To the students and to the young physicians should be given a training with a broad foundation on which they can build themselves into the best type of clinicians. In such a training the art of good observation, the cultivation of memory, of logic and of technical skill, as well as the development of personality are essential. Diagnostic opinions should be expressed clearly and in writing. Dr. Christian states that ". . . often cowardice prevents such commitments." He criticizes the present tendency to say that the mass of literature is so great that no one can keep up with it. "To my mind this is but an excuse of the lazy." Specialization is essential but must be based on broad experience. He quotes Osler, who spoke of Jonathan Hutchinson as ". . . the only great generalized specialist which the profession has produced."

Dr. Christian, referring to himself, says ". . . the hospital physician busied daily in the care of patients, in contact with students, resident staff, associates and colleagues; this seemed to me the acme of attainment when in the days of my youth I dreamed dreams."

Traditions are to be cherished only if they represent the best in the professions. It is for this reason that Dr. Christian's report, an expression of need for a harmonious balance in medicine, is of importance to the profession.

A NEW INTERPRETATION OF A PARAGRAPH IN THE HIPPOCRATIC OATH

The paragraph referring to lithotomy in the Hippocratic Oath, οὐ τεμέω δὲ οὐδὲ μὴν λιθιῶντας, ἐκχωρήσω δὲ ἐργάτησιν ἀνδράσι πρῆξις τῆσδε, is one of the most confusing in classical literature. It has been generally assumed that the oath forbids the performance of lithotomy. The two usual justifications for this injunction are (1) that the operation was often fatal and was therefore delegated to another expert group, and (2) that the oath indicates the beginning of specialization in Greek medicine as already existed in Egypt. These appear to a recent student of history to be absurd. Savas Nittis¹ states that sufficient grammatical and linguistic consideration has never been given to this paragraph. Instead a meaning was assumed and explanations for the injunction against lithotomy were sought afterward. Nittis proposes a new interpretation of the paragraph. His translation, for which gram-

1. Report of the Physician-in-Chief, Twenty-Fifth Annual Report of the Peter Bent Brigham Hospital for the year 1938, 1939, p. 92.

1. Nittis, Savas: The Hippocratic Oath in Reference to Lithotomy: A New Interpretation with Historical Notes on Castration, Bull. Hist. Med. 7: 719 (July) 1939.

matal and etymological reasons are given, would be as follows: "I will not cut, indeed not even sufferers from stone, and I will keep apart from men engaging in this deed." Since surgery could not be forbidden in those early times, the injunction in the oath, it is said, must refer to some abomination, such as castration, since *τέμνειν* means "to castrate."

Lithiasis was a common complaint in the early centuries in the Near East and still is. It must have required much attention by physicians; then instruments were invented for locating stone in the bladder. Who would seriously contend, therefore, that the ethical surgeon who performed these diagnostic procedures was prevented from doing lithotomy by an oral oath or a written contract? Celsus, who described lithotomy in the first century, was copying from an earlier Greek source. Comment by Aretaeos indicates that lithotomy was frequently performed by the best representatives of the Hippocratic school. Naturally serious complications often followed such an operation. Death frequently ensued and, if the patient survived, a resulting fistula often made life unbearable. Since the only relief came from cutting in the region of the urethral orifice of the bladder, necrosis of the testicles must have frequently followed lithotomies as a result of occlusion of the spermatic artery. Since it would have been easier for the surgeon to remove the interfering external genitalia before the lithotomy was performed, Nittis suggests, that practice was probably followed by some surgeons. Indeed, Nittis asserts that castration probably was the most frequently performed operation in ancient times.

In the *Odyssey* there is mention of an establishment where men were sent for castration. Herodotus speaks of one Panionios, of Chios, who "made his living from a most unholy trade. Whenever he came into possession of boys with good looks he castrated them and, bringing them to Sardis and Ephesus, sold them for a good price." In Rome, where the vices of Greece were imitated, castration for commercial or immoral purposes was usually carried out by the *magrones*, a special group of practitioners. While the regular physician probably performed castrations occasionally for some legitimate cause, neither Hippocrates nor Aristotle advised castration. During the early Christian era the number of castrates must have been impressive, for the first Ecumenical Council of Nice provided in its first canon to permit holy orders to a man "if he had been castrated by a physician on account of illness." During the Middle Ages, castration was advocated for the cure or prevention of many diseases, and until recently it was sometimes performed for the cure of epilepsy. In Europe following the renaissance, castration found widespread application for the prevention and cure of hernia. The general opinion that the castrated singers in the churches of Rome did not suffer from hernia promoted the idea. During the eighteenth century this abuse reached alarming proportions. The

physician was free to use or abuse his judgment without legal restrictions in Greek society. Laws did not exist to penalize the physician or to award damages for malpractice to the patient or his family. In the oath, Hippocrates attempted to formulate the essential moral obligations of the physician and, according to Nittis, to prevent the practice of this abominable operation.

TRAVELING FACULTIES IN GRADUATE MEDICAL EDUCATION

The problem of continuation study for practicing physicians is no longer one concerned exclusively with education; transportation is beginning to be of considerable importance. A graduate program may be quite sound educationally and yet fail if it does not bring competent instructors to physicians desirous of continuing their studies. This is especially true in the more sparsely settled areas of the United States and in those states without medical schools.

For the past five years the physicians of Idaho have appreciated the need for continuation study. To meet this need they have brought to the five day annual meeting of their state association a flying medical faculty. Each year five or six instructors from one medical school have been invited to organize an integrated, correlated course of study of general interest to practicing physicians. Instruction in basic sciences has initiated discussions of clinical studies, and round table discussions have permitted attending physicians to participate. Expenses of the traveling faculty have been paid by the state association, since registration fees of \$5 or \$10 have been adequate to finance these programs.

In 1939 the state medical associations of Washington and Oregon arranged their annual meetings to utilize the same traveling faculty as was engaged in Idaho. Thus the physicians of three states have had the opportunity to attend, at their annual meetings, a continuation course. Attendance has been enhanced, and it has been possible to bring to each state systematic instruction at less expense than is ordinarily required.

Four other western states, Colorado, Utah, New Mexico and Wyoming, have pooled their interests in graduate studies to bring, every two years to one of their states, twenty out of state speakers to discuss problems of medicine and public health which are peculiar to the Rocky Mountain region. The medical society in each state has been represented on the executive committee and a different state society has acted as host every two years. The first Rocky Mountain Conference was held in Denver in 1937, the second in Salt Lake City in 1939, and the next meeting is scheduled for Wyoming. A registration fee of \$3 has been sufficient to finance this effort.

Thus seven states, five without a four year medical school within the borders of the state, have provided

See Graduate Medical Education: Idaho, Oregon and Washington, in the Organization Section, this issue.

graduate opportunities for practicing physicians. Frequently physicians travel from 100 to 250 miles to attend one or two day regional meetings.

There still remain, however, physicians who are unable to leave their practice even for a short time to travel the distance required. For them provision is now being made, the instructors traveling throughout the state so that continuation study may be brought to a greater number of communities.

Current Comment

NOBEL PRIZE TO PROFESSOR DOMAGK

The Nobel Prize for Medicine was recently awarded to Prof. Gerhard Domagk, whose name is indelibly associated with the drug sulfanilamide and its derivatives. Domagk was born in Lagow, Germany, in 1895. His principal early work was in the field of pathology. After teaching at Greifswald and Muenster universities he became director in 1927 of the Institute of Experimental Pathology of the I. G. Dye Works in Elberfeld. Late in 1932 he first demonstrated the curative effects of prontosil (now neoprontosil) in the streptococcal infections of mice. After many careful observations, the details of the new discovery were finally published by Domagk in medical and scientific journals early in 1935. He had earlier received the Emil Fischer Medal, highest award of the German Chemical Society, in 1937 and the Cameron Prize of the University of Edinburgh in 1939.

RABIES

The study of rabies conducted by the International Health Division of the Rockefeller Foundation in cooperation with the Alabama State Board of Health already has been prosecuted to the point where the building program has been completed.¹ The total expenditures for public health work in this field have come to more than \$108,000 for the four years 1935 to 1938 inclusive. Particular attention is being directed to a study of the efficacy of preventive measures in rabies. Alabama, with an estimated dog population of 450,000, vaccinated 220,000 dogs during 1937, the first year the compulsory law went into effect. During 1938, 134,000 dogs were vaccinated and nearly 18,000 killed as strays. Attempts have also been made to determine whether the rat plays a part in the spread of rabies, but so far experiments of this nature have been negative. All attempts to cultivate rabies street virus have been unsuccessful. A fixed strain obtained from the Alabama State Board of Health has been carried through sixty-eight transfers without difficulty. As yet it has been impossible to obtain growth on the chick embryo. A report on the effect of various diluents acting for short periods on the rabies virus in high dilutions has also been made. A fruitful outcome to these investigations would be of tremendous benefit to many portions of the country in which rabies remains endemic.

CHRONIC LEUKEMIA

Because of the characteristic insidious onset of the leukemias they are usually first recognized only after widespread anatomic and physiologic abnormalities have developed. Wintrobe and Hasenbush¹ reviewed all cases of chronic leukemia in adults observed at the Johns Hopkins Hospital between January 1926 and August 1938, collecting thirty-nine cases of myelogenous and forty-seven cases of lymphogenous leukemia for study. Five of the patients who subsequently developed typical chronic myelogenous leukemia were found to have unexplained leukocytosis in the absence of typical leukemic signs or symptoms. The discovery was made in the course of routine examination following pregnancy in one case, for sterility in another, because of symptoms suggestive of disease of the gallbladder in the third, for abdominal distress in the fourth, and because of uterine myomas in the last. A reasonable estimate of the time elapsing from the onset of chronic myelogenous leukemia until symptoms of the disease commonly cause the patient to seek medical attention is probably from two to five years or longer. Data concerning the early phase of chronic lymphogenous leukemia were available in sixteen cases. The disease was first discovered in three men aged 59, 67 and 72 when examined for symptoms due to prostatic hypertrophy. Other patients were examined because of sugar in the urine, a psychoneurotic disorder and "indigestion." Unlike myelogenous leukemia, the finding of unexplained leukocytosis was the first evidence of the disease in only about one third of the cases of early lymphogenous leukemia. In another third, glandular enlargement was the sign which first attracted attention. The time interval between the observation of signs suggesting lymphogenous leukemia and the development of symptoms of the disease was from one and one-half to two and one-half years. The earlier recognition of lymphogenous leukemia, as compared with that of myelogenous leukemia, is explained, these authors believe, by the greater frequency with which glandular enlargement sufficient to attract attention occurred in the patients with the former. Males predominated in both groups. In 72 per cent of the cases of myelogenous leukemia the age of onset was between 30 and 59 years, while in 61.7 per cent of the cases of lymphogenous leukemia symptoms began between 50 and 69 years. In addition to the unexplained leukocytosis so frequent in early chronic myelogenous leukemia, distinct lymphocytosis was found commonly characteristic of early lymphogenous leukemia even when the leukocyte count was relatively low. Solution of potassium arsenite was without value in lymphogenous leukemia and of less value than irradiation in myelogenous leukemia. Response to irradiation was slightly better in myelogenous than in lymphogenous leukemia. Contrary to the frequently expressed opinion, infections in the majority of cases did not produce a remission in physical signs or the blood picture. Persistent unexplained leukocytosis must therefore be considered a premonitory sign of chronic myelogenous leukemia, and persons in whom it occurs should be carefully studied with that disease in mind.

ORGANIZATION SECTION

GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

WASHINGTON

WASHINGTON STATE MEDICAL ASSOCIATION

On Aug. 30, 1939, the House of Delegates of the Washington State Medical Association resolved that a program for providing postgraduate medical education in the state of Washington be developed by the postgraduate medical education committee under the general supervision of the board of trustees. This committee, with Dr. Homer D. Dudley as chairman, has considered the postgraduate experiences of various state societies. On the basis of these studies the committee has recommended the following program:

1. Continuation of the graduate medical course for physicians throughout the state given annually in cooperation with the King County Medical Society and the Extension Division of the University of Washington with the additional assistance of the postgraduate committee of the state medical association, the association aiding in the arrangements and in publicity.

2. Inauguration of circuit courses by out of state lecturers under the supervision of the committee by providing defined lecture districts, securing competent speakers for a series of five days' instruction in each locality, including clinics, stressing subjects chosen by the physicians of each district, and by charging registration fees adequate to finance the regional program.

3. Provision of speakers from the membership of the state association to supplement the out of state lecturers. This will be made from a list compiled by the association. From the list component county medical societies may choose competent Washington physicians, and each society will be expected to finance their expenses.

4. Desirability of having other committees concerned with medical education consult with the committee. The postgraduate committee has emphasized this so that all postgraduate activities within the state may be properly correlated and coordinated.

The 1939 annual meeting of the Washington State Medical Association, held in Spokane, was devoted to graduate instruction. Five instructors from Washington University School of Medicine, St. Louis, were engaged in a cooperative agreement with the state medical associations of Oregon and Idaho. At the three day annual meeting, subjects discussed included cancer, chemotherapy, cholecystography, infant feeding, pneumonia, puerperal infection and toxemias of pregnancy. Attendance totaled 460 physicians. Of the 2,123 physicians in the state of Washington, 1,468 are members of the state medical association.

WASHINGTON STATE DEPARTMENT OF HEALTH (Instruction in Obstetrics and Pediatrics)

Previous to 1938 the education program of the Washington State Department of Health for physicians practicing in the state had been carried on through itinerant child health conferences. It was proposed in 1938 that the itinerant conferences be held only as a means of introducing a clinic or of determining the need for a clinic in a given area, the educational program to consist largely of a refresher type of course by recognized authorities in obstetrics or pediatrics. An out of state physician and Washington physicians were to consider such subjects as endocrinology, internal medicine, nutrition and dental problems.

In May 1938 an out of state obstetrician gave three days of lectures and conferences in each of seven cities of the state. The committee on maternal and child welfare of the state medical association cooperated in sponsoring this program. A \$2 registration fee was charged. The course of six lectures was attended by 217 physicians.

The chairman of the committee on maternal and child welfare, Dr. H. H. Skinner, recommended in 1938 that the committee membership be made permanent and that the committee be composed of an equal number of obstetricians and pediatricians serving overlapping five year terms.

In 1938 a committee of eight was formed as a permanent committee on medical cooperation and participation in the maternal and child hygiene program of the state department of health. On this committee were three representatives of the Washington sections of the North Pacific Pediatric Society, three of the Washington State Obstetrics Association and the director of the state department of health and the chief of the division of maternal and child hygiene. This committee now acts in an advisory capacity to the health department.

During May 1939 the division of maternal and child hygiene of the state department of health and the committee of eight jointly sponsored a three day series of afternoon and evening lectures in seven cities of Washington and in Vancouver, B. C. The assistance of county medical societies was enlisted in each locality and the secretaries were provided with post card announcements. An out of state medical school instructor gave six lectures on heart diseases, hemorrhage and toxemias of pregnancy, obstetric analgesia and cesarean sections in each center. Six hundred and thirteen physicians was the total attendance recorded. No registration fees were charged, since the state department of health provided financial support.

UNIVERSITY OF WASHINGTON

The University of Washington, Seattle, in cooperation with King County Medical Society, has conducted a five day graduate medical course during July each year since 1916. Dr. David C. Hall is executive secretary of the course and Dr. Raymond L. Zech was chairman of the county society committee of fourteen in 1939. There is also a committee of five staff members of the King County Hospital responsible for organizing clinical instruction. Every year four or more out of state physicians are engaged as a faculty, and in July 1939 five members of the faculty of Northwestern University Medical School, Chicago, and a member of the United States Public Health Service participated. Local physicians supplement the guest speakers by providing clinics. Instruction is scheduled from 9 a. m. to 10 p. m. daily. Major subjects of medicine are included and in case discussions two or three physicians participate, stressing the various approaches to the problems presented. Lectures are held on the university campus and clinics and demonstrations are given at the county hospital by members of the staff. Didactic lectures are limited to from forty to fifty minutes and clinics to from ten to twenty minutes. Medical and surgical clinics considered thirteen of the various specialties of surgery and three of the special subjects of medicine in 1939. Daily demonstrations were held in pathology, roentgenology and anesthesia as well as scientific exhibits in other subjects.

The extension division of the university aids in administering the course. A registration fee of \$10 is charged which has provided sufficient support. Every physician in the state is sent a notice; announcements are published in *Northwest Medicine*. Annual attendance has ranged from 207 to 311 physicians.

LIBRARY SERVICE

The King County Medical Society, in addition to the active participation of its members in the annual graduate programs at the University of Washington, has provided library facilities for physicians practicing in the vicinity of Seattle. Space has been provided in the Cobb Building, Seattle, with adequate stacks and reading rooms. There are 11,468 volumes, three fifths of which are periodicals, a total of 233 being regularly

received. Ten dollars from the annual dues of every county society member supports the library. About two thirds of the members of the society used the library in 1938, as well as approximately 200 other physicians. The package lending service is available to individuals or to other libraries. Out of town physicians must supply postage. During 1938, 6,300 items were circulated.

Libraries with paid librarians are also maintained by the Spokane County Medical Society and the Pierce County Medical Society, the facilities being available to physicians practicing in the vicinity of Spokane and Tacoma.

OTHER GRADUATE ACTIVITIES

The Seattle Surgical Society provides a two day program each year. The Spokane Surgical Society, the Puget Sound Surgical Society and the Tacoma Surgical Society present annual graduate days. One or more guest speakers are provided to discuss cases presented by Washington physicians. Members of state medical associations are invited to attend. Registration fees vary from \$2 to \$3.

IDAHO

IDAHO STATE MEDICAL ASSOCIATION

At the September 1933 meeting of the House of Delegates of the Idaho State Medical Association, it was recommended by Dr. J. N. Davis that graduate study be considered and that the advisability and feasibility of securing members of medical school faculties for an annual continuation course be determined.

In September 1934 the house of delegates authorized the president of the state association, Dr. Charles R. Scott, to appoint a committee of six members to arrange a graduate course for the next annual meeting. Fifteen hundred dollars was the initial allocation for financing the state association's graduate program.

In planning the course of instruction certain principles were elaborated, since it was felt that the medical association had two primary obligations, first, to improve medical care and, second, to enlighten the public on personal and public health. It was decided that five days should be devoted each year to an integrated and correlated course of instruction in subjects of general interest selected on suggestions of physicians. Five instructors from a different medical school each year would organize as a traveling faculty, thus providing a harmonized course. Each day five or six fifty minute lectures would be scheduled with additional round table discussions.

The state association has assumed responsibility for financing its graduate program. In 1936, when the constitution and by-laws of the association were modified, the Idaho Medical Foundation was established with the members of the council as trustees of the foundation. A foundation fund of \$10,500 was established by contributions from members of the state association which constituted a percentage of fees which they had received for the care of special groups of patients. The income from the foundation's funds is available for financing graduate activities. This has not been necessary, however, since registration fees of \$5 or \$10 have been sufficient to meet each year's expenses. Each speaker is given an honorarium and his traveling expenses.

The committee on scientific work of the state association is a standing committee consisting of three members, one selected each year to serve three years. The present chairman of this committee is Dr. C. W. Pond. Ex officio members are the president and the secretary-treasurer of the association. The secretary acts with the committee on scientific work in arranging the annual graduate program.

Beginning in 1935 a traveling faculty from the following medical schools has participated each year: Northwestern University Medical School, University of California Medical School, University of Minnesota Medical School, University of Michigan Medical School and Washington University School of Medicine. In 1937 Idaho physicians presented clinical cases for discussion in local hospitals to supplement the faculty lectures. Attendance has varied from 116 to 144. Of the 406 physicians in Idaho, 272 are members of the state association.

IDAHO STATE DIVISION OF PUBLIC HEALTH

In November 1936 the Idaho State Division of Public Health, in cooperation with the Idaho State Medical Association, conducted an itinerant postgraduate lecture course in six cities of

the state. Three out of state physicians participated in the one and two day afternoon and evening sessions in obstetrics and pediatrics. The chairman of the state association's committee on scientific work arranged the program and selected the speakers. The county medical society in each locality arranged the details for each meeting. The course was attended by 181 physicians; no registration fees were charged. The health division financed this effort.

During 1937 instruction in pediatrics was provided in two cities of the state by one out of state physician. Attendance at these lectures approximated seventy-five.

In April and May 1938 four out of state physicians conducted a postgraduate course in pediatrics, dermatology and syphilology and orthopedics in five cities of the state. One day sessions were held in four places and two days were allowed in a fifth. Meetings were held in hotels and in two cities; clinical demonstrations were attempted. Approximately 150 physicians attended the 1938 itinerant course.

Lectures in syphilology, pediatrics, orthopedics and general medicine were given in the spring of 1939. Three out of state physicians participated in one day meetings held in five localities. One hundred and seventy physicians enrolled. No registration fees were charged.

IDAHO ANTI-TUBERCULOSIS ASSOCIATION

During the past two years the Idaho Anti-Tuberculosis Association has offered a consultation service to practicing physicians of the state in the interpretation of roentgenograms. The consultant also participates in the activities of the state division of public health.

OREGON

OREGON STATE MEDICAL SOCIETY

At the 1939 annual meeting of the Oregon State Medical Society three out of state faculty members who had participated in the annual meetings in Idaho and Washington took part in the scientific program. A fourth guest speaker was also included. This enabled the committee on scientific work to provide members of the association with an integrated general course of twelve lectures in pediatrics, obstetrics, surgery and medicine. Round table discussions were held and twenty-four contributions were made by Oregon physicians on other subjects. The three and one-half day session was devoted substantially to postgraduate instruction and, by the cooperative agreement with the medical societies of two adjoining states, it was possible to present a comprehensive and instructive program. There are 805 members of the Oregon State Medical Society of the 1,386 physicians in the state.

At the June 1939 meeting of the council of the state medical society the president of the society, Dr. Charles E. Sears, was authorized to appoint a committee on postgraduate medical education. Dr. Karl H. Martzloff was made chairman of a committee of five members. This committee met in September 1939 to discuss the establishment of a graduate program.

The Oregon State Medical Society, in cooperation with the Oregon State Board of Health, provided one or two days of lectures in obstetrics and pediatrics in nine cities of the state this year. The committee on maternal welfare, Dr. Raymond Watkins, chairman, with the director of the division of maternal and child health, Dr. G. D. Carlyle Thompson, arranged the lecture series for May 1939. Each component medical society which participated selected topics from a list of twelve subjects outlined by the out of state obstetrician and pediatrician engaged to give the instruction. From six to ten afternoon and evening lectures were held in each center, except one in which the instruction began at 9 a. m. Two hundred and seventy-seven physicians from twenty-one counties enrolled. No registration fees were charged, since the program was supported by federal funds.

The Oregon Academy of Ophthalmology and Otolaryngology and the University of Oregon Medical School have provided a week of lectures and clinics at Portland for ophthalmologists and otolaryngologists over the past four years. While the course is primarily intended for physicians in special practice, subjects of general interest to practicing physicians are included. Surgical anatomy of the head and neck is demonstrated at the medical school and two out of state speakers present didactic

ORGANIZATION SECTION

1741

instruction. This is followed by round table discussions and outpatient clinical exercises. A registration fee of \$25 is charged. The average number of physicians attending is sixty. The University of Oregon Medical School has developed a traveling clinic under its child guidance program and during 1937-1938 established thirteen centers over the state. Teams consisting of three instructors from the medical school have

constituted the staff of this traveling clinic and when a district was visited these instructors were available for discussions and demonstrations before the local medical society. The University of Oregon Medical School provides library facilities for practicing physicians. During 1938-1939, 499 Oregon physicians and thirty-eight physicians from other states made use of the library.

"BOOTLEG" AUTOMOBILE EMBLEMS

Years ago the American Medical Association had copyrighted the design used on the official A. M. A. auto emblem. The design comprised essentially the Aesculapian (knotty) rod entwined by one serpent placed on the center of a green cross, with the letters M.D. beside the rod. The use of this official emblem has been restricted to members of the American Medical Association and thousands of the emblems have been manufactured and distributed in this way to be placed on physicians' cars, sometimes including also the name of the constituent society of which the physician is also a member. Several imitations or bootleg auto emblems have since appeared on the market. The design used by the imitators is different, comprising a straight rod with wings at the top and entwined by two serpents. The bootleg emblem is distributed by unofficial agencies who make no effort to determine that purchasers are physicians. Members of the American Medical Association should beware of imitation emblems. The official auto emblem bears a serial number in the small panel, which is registered at the headquarters of the American Medical Association with the name of the user and thus becomes an authoritative means of establishing one's identity in troublesome traffic situations. Keen observers can readily distinguish between the official emblem and bootleg auto emblems.

WOMAN'S AUXILIARY

ANNUAL MEETINGS

Mrs. Rollo K. Packard, president of the Woman's Auxiliary to the American Medical Association, addressed annual meetings of auxiliaries to the following state medical societies: Kentucky at Bowling Green September 13, Michigan at Grand Rapids September 19, Pennsylvania at Pittsburgh October 2, Virginia at Richmond October 4 and Delaware at Wilmington October 10.

The annual meeting of the auxiliary to the Indiana State Medical Association was held in Fort Wayne October 10-12. Mrs. Maurice B. Van Cleave is the retiring president.

The annual meeting of the auxiliary to the State Medical Society of Wisconsin was held in Milwaukee September 12-14. Dr. Rock Sleyser, President of the American Medical Association, addressed the auxiliary. Mrs. Robert E. Fitzgerald is the retiring president and Mrs. Frank W. Pope is president 1939-1940.

The annual meeting of the auxiliary to the Utah State Medical Association was held in Salt Lake City, September 5-7, during the time of the meeting of the Rocky Mountain

Medical Conference. Speakers at the meeting were: Dr. Claude L. Shields, president of the Utah State Medical Association; Dr. E. M. Neher, chairman of the advisory council to the auxiliary; Dr. J. W. Aird, the oldest physician in the practice of medicine in Utah, and Dr. Edward Jackson, guest speaker from Denver. Mrs. W. M. Stookey, retiring president, presided. Mrs. J. J. Weight, Provo, is president 1939-1940.

Northeast Mississippi Thirteen Counties Auxiliary met in Aberdeen September 12. Mrs. V. B. Philpot is president of this group. Dr. W. H. Anderson, Boonville, president-elect of the Mississippi State Medical Association and editor of the *Mississippi Doctor*, spoke, presenting the objective of the state medical association. The auxiliary will assist the association in its program of securing satisfactory legislation on vital statistics, food and drugs, an antibarbituric acid law and the revision of the mortmain law, which at present forbids bequests of property to orphanages, hospitals, colleges and the like which are related to a church. Mrs. Hugh H. Johnston, president, reports a membership of 312.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

First Full Time Professor of Medicine.—Dr. Raymond L. Gregory, professor of medicine at Howard University College of Medicine, Washington, D. C., has been appointed professor and head of the department of medicine at the University of Arkansas School of Medicine, Little Rock, newspapers report. This is said to be the first full time appointment to the position. Dr. Gregory graduated at the University of Minnesota Medical School in 1929 and has served on the faculties of the medical schools of the University of Iowa and Louisiana University. He has been associated with Howard since 1937. Dr. Silas C. Fulmer has been professor of medicine at the University of Arkansas and acting part time head of the department.

CALIFORNIA

Society News.—The staff of Providence Hospital presented the following program before the Alameda County Medical Association in Oakland October 16: Drs. Philip J. Dick, "Rectal Polyps"; Malcolm B. Hadden, "Russell Traction and Treatment of Fractured Femurs"; Robert S. Peers, "Gout and Arthritis—Differential Diagnosis," and Lester B. Lawrence, "Intraspinal Tumors—Comments on Diagnosis."—At a meeting of the Los Angeles Surgical Society October 13 Drs. Rupert B. Raney spoke on "Complications of Cranioerebral Trauma Benefited by Surgery" and Mark A. Glaser, "A New Regime for Treatment of Head Injuries."—A symposium on sulfanilamide and sulfapyridine was presented before the San Francisco County Medical Society October 10 by Drs. Arthur Haim, Dwight L. Wilbur, Donald A. Dallas, Edward B. Shaw, Thomas E. Gibson and Jesse L. Carr.—The San Mateo County Medical Society was addressed in San Mateo October 25 by Drs. Mayo H. Soley and Paul A. Glielbe, both of San Francisco, on "Physiologic Syndromes Which Simulate Organic Disease."

Railway Surgeons' Meeting.—The thirty-seventh annual convention of the Pacific Association of Railway Surgeons was held at the Cliff Hotel, San Francisco, September 29-30 with the following speakers among others:

- Dr. Lionel D. Prince, San Francisco, A Method of Treatment of Fractures of the Patella.
- Dr. Ralph M. L. Dodson, Portland, Ore., Fractures of the Transverse Processes of the Lumbar Vertebrae.
- Dr. Howard A. Brown, San Francisco, The Neurologic Aspects of Low Back Pain and Sciatica.
- Dr. Leo L. Stanley, San Quentin, Testicular Substance Implantation.
- Dr. Charles R. L. Mathe and Robley C. Archambeault, M.A., San Francisco, Spectrographic Analysis of Urinary Calculi: A Preliminary Report.
- Dr. Edward M. Butt, Los Angeles, Virus Infections.
- Dr. Eugene S. Kilgore, San Francisco, The Management of Coronary Disease in Engineers.
- Dr. Grant L. Selfridge, San Francisco, Deafness.
- Drs. Charles A. Thomas and Shirley C. Davis, both of Tucson, Ariz., Tuberculosis in the Aged.
- Dr. Edmund J. Morrissey, San Francisco, A New Test for Circulatory Disturbances in the Hand.
- Dr. Lloyd B. Crow, San Francisco, Roentgenologic Demonstration.

Dr. Richard J. Flamson Jr., Los Angeles, gave the presidential address on "The Status of the Railway Surgeon."

FLORIDA

East Coast Meeting.—The Florida East Coast Medical Association will hold its annual meeting at Ponte Vedra November 10-11. The speakers will include:

- Dr. Clarence Larimore Perry, Miami, Differential Diagnosis and Treatment of Vulvar Granuloma Inguinale.
- Dr. Claude Anderson, Orlando, Intrathoracic Goiter or Adenoma of the Thyroid.
- Dr. Isaac M. Hay, Melbourne, Endometriosis.
- Dr. Eugene L. Jewett, Orlando, Fractures of the Femur.
- Dr. James C. Nowling, West Palm Beach, Acute Meningitis Caused by Influenza Bacillus.
- Dr. James J. Nugent, Miami, Pyelonephritis—Recent Improvements in Treatment.

A symposium on management of chest tumors will be presented by Drs. Louie M. Limbaugh, Raymond H. King, Wilfred McL. Shaw and Kenneth A. Morris. All are from Jacksonville. Dr. Frank K. Boland, Atlanta, Ga., will be the guest speaker at this meeting.

ILLINOIS

Free Pneumonia Serum and Sulfapyridine.—The state department of health announces that during the current pneumonia season both serum and sulfapyridine will be distributed free. To obtain them, physicians must have specimens from patients tested in approved laboratories for the type of pneumonia involved and must agree to render reports to the department. Deaths occurred at the rate of 94 per thousand among serum-treated patients against 150 per thousand among comparable nonserum-treated patients during the first half of 1939. These two groups were all from a list of 2,100 patients from whom specimens were taken and tested in approved laboratories. The serum and sulfapyridine may be obtained from the centers which have been established throughout the state.

Chicago

Personal.—Miss Ailee H. Miller, Gainesville, Fla., has been appointed director of public health for the Tuberculosis Institute of Chicago and Cook County, succeeding Mrs. Adelaide Ross, resigned.

Koessler Fellowship Awarded.—Dr. James J. Smith, St. Louis University School of Medicine, class of 1937, has been awarded the Jessie Horton Koessler Fellowship of the Institute of Medicine of Chicago. Under the fellowship, which carries a stipend of \$500, Dr. Smith will work with Dr. Andrew C. Ivy at Northwestern University Medical School in research on evacuation of the gallbladder in pregnancy.

Ophthalmology for General Practitioners.—The Illinois Eye and Ear Infirmary announces that a course in refraction and diseases of the eye will be offered during the week of December 4 for general practitioners in towns outside of Cook County and not nearer than 25 miles to an ophthalmologist. The course will be limited to six men and the fee will be \$25. Information may be obtained from the dean of instruction, Illinois Eye and Ear Infirmary, 904 West Adams Street.

Society News.—The Chicago Society of Internal Medicine will be addressed November 27 by Drs. Michael H. Streicher on "Appendicitis—Incidence of Amebiasis in a Clinical Review of 3,407 Cases"; Ralph B. Bettman and Gemma M. Lichtenstein, "Acute Cholecystitis" and Laurence E. Hines, Allen H. Hoover and Edwin C. Graf, "Effect of Sulfanilamide on the Fibrinolytic Activity of Hemolytic Streptococci."—The Chicago Laryngological and Otological Society will be addressed November 6 by Drs. Hans Brunner on "Surgical Repair of Facial Paralysis"; Frank J. Novak Jr., "Giant Follicular Hypertrophy of Nasopharynx," and William A. Smiley, "Subglottic Polyp Following Intratracheal Anesthesia."

Symposium on Nutritional Deficiency.—The Chicago Medical Society will sponsor a symposium on nutritional deficiency at Thorne Hall, Northwestern University Medical School, November 15 with the following speakers: Dr. Tom D. Spies, Cincinnati; Dr. Frederick T. Jung, Smith Freeman, Ph.D., Dr. Warren H. Cole, Chester J. Farmer, A.M., Drs. Arthur F. Abt, Don C. Sutton, John Ashworth, Nathan S. Davis III, Edward D. Allen, Bengt L. K. Hamilton, Howard L. Alt, Charles B. Puestow and Clifford J. Barborka and Franklin C. Bing, Ph.D. The symposium will begin at 9 o'clock in the morning, and in the evening following dinner at the Chicago Woman's Club Dr. Spies will discuss "Vitamin B and Pellagra."

INDIANA

State Medical Election.—Dr. Albert M. Mitchell, Terre Haute, was chosen president-elect of the Indiana State Medical Association at its annual meeting in Fort Wayne October 12. He will take office in January 1941. Dr. Karl R. Ruddell, Indianapolis, will be inducted into the presidency in January 1940. The 1940 session of the association will be held in French Lick.

Society News.—The Fort Wayne Medical Society was addressed recently by Dr. Richard W. Terrill, Fort Wayne, on "Treatment of Foreign Bodies in the Eye."—At a meeting of the Montgomery County Medical Society in Crawfordsville September 21 Dr. George S. Bond, Indianapolis, discussed coronary disease.—Dr. Arthur N. Ferguson, Fort Wayne, spoke on heart disease at a recent meeting of the Whitley County Medical Society in Columbia City.

District Meeting.—The sixty-second semiannual meeting of the Eleventh Indiana Councilor District Medical Association was held at Marion October 18. In the morning Dr. Quitman U. Newell, professor of clinical obstetrics and gynecology, Washington University School of Medicine, St. Louis, conducted a clinic and in the afternoon the following spoke: Drs. Cyrus J. Clark, Indianapolis, "Sulfapyridine and Allied

MEDICAL NEWS

1743

Therapy in Treatment of Pneumonia"; Charles L. Wise, Camden, "Is Convalescent Serum of Value?" and Carl P. Huber, Indianapolis, "Recent Trends in the Investigation and Treatment of Sterility." Dr. Newell addressed the banquet session in the evening.

KANSAS

New Health Director for Kansas City.—Dr. Ragnar T. Westman, formerly health officer of Bay County, Mich., has been appointed city health director of Kansas City, succeeding the late Dr. William F. Lunsford. Dr. Westman graduated at the University of Minnesota Medical School, Minneapolis, in 1931. He formerly served as chief quarantine officer of Minneapolis.

Postgraduate Courses.—Two postgraduate courses on obstetrics and pediatrics began in various sections of south central and southeastern Kansas October 23 to continue through November 17. The speakers are Drs. John H. Randall and William F. Mengert, State University of Iowa College of Medicine, Iowa City; Morris Edward Davis and William J. Dieckmann, Department of Medicine of the Division of Biological Sciences, University of Chicago; Mandel L. Spivek of the Children's Memorial Hospital, Chicago, and Julian D. Boyd, associate professor of pediatrics at Iowa.

LOUISIANA

Society News.—At the joint scientific and third quarterly executive meeting of the Orleans Parish Medical Society October 9 Dr. Earl Conway Smith discussed treatment of trichomonas vaginalis vaginitis; Dr. Rufus H. Alldredge, "Fractures of the Humerus," and Dr. Donovan C. Browne, "Gastroscopy—Its Relation to Surgery." All are of New Orleans.

Personal.—Dr. Erasinus D. Fenner, New Orleans, has presented to the library of the school of medicine of Louisiana State University a collection of medical books and journals from his library.—Dr. Edgar Hull, assistant professor of medicine, Louisiana University Medical Center, New Orleans, has been appointed acting head of the department of medicine to succeed the late Dr. George S. Bel.

Dr. Tripoli Appointed Professor.—Dr. Carlo J. Tripoli has been appointed professor of medicine in charge of the department of medicine of the Graduate School of Louisiana State University, New Orleans. A graduate of Tulane University of Louisiana School of Medicine, New Orleans, class of 1929, Dr. Tripoli has been serving on the staff of the state university since 1931; he has been assistant professor of medicine since 1938. He is also chairman of the section on medicine of the state medical society.

MASSACHUSETTS

Dr. Schall to Succeed Dr. Mosher.—Dr. Lcroy A. Schall, instructor in laryngology, Courses for Graduates, Harvard Medical School, Boston, has been promoted to the position of Walter Augustus Lecompte professor of otology and professor of laryngology, succeeding Dr. Harris P. Mosher, who becomes professor emeritus. Dr. Schall graduated at Jefferson Medical College of Philadelphia in 1917. He has served as surgeon in otolaryngology at the Massachusetts Eye and Ear Infirmary; vice chairman of the Section on Laryngology, Otology and Rhinology, American Medical Association, Chicago, 1936-1937, and secretary from 1937 to 1939. Dr. Mosher has for many years been president of the American Board of Otolaryngology. He was chairman of the Section on Laryngology, Otology and Rhinology of the American Medical Association for the year 1932-1933 and president of the American Academy of Ophthalmology and Otolaryngology in 1929.

Clinical Conference on Physical Medicine.—The New England Society of Physical Medicine will hold a clinical conference at the Hotel Kenmore, Boston, November 8-9 with a special session at the Massachusetts Institute of Technology the morning of November 10. The speakers will include:

Dr. Harold E. Himwich, Albany, N. Y., Nitrogen Therapy: Physiologic Aspects in Schizophrenia.
Dr. Charles W. McClure and Isaac R. Jankelson, Boston, Gastroscopy.
Dr. Temple S. Fay, Philadelphia, Observations on Human Refrigeration.
Dr. William H. Schmidt, Philadelphia, Surgical Diathermy.
George R. Harrison, Ph.D., Cambridge, Mass., Modern Physics and the Modern Physician.
Harold E. Edgerton, Sc.D., Cambridge, Seeing the Unseen with Stroboscopic Photography.
Dr. Edward A. Edwards, Boston, and Seibert O. Duntley, Sc.D., Cambridge, The Pigments and Color of Living Human Skin.
Dr. Rebekah Wright, Boston, Hydratic Sedatives.

The program also includes symposiums and demonstrations covering a wide range of subjects in the field of physical

medicine. For the special session at Massachusetts Institute of Technology the lecturers will be: Joseph W. Horton, Sc.D., associate professor of biologic engineering; Arthur C. Hardy, Sc.D., professor of optics and photography; Robley D. Evans, Ph.D., associate professor of physics, and John G. Trump, Sc.D., assistant professor of electrical engineering.

MICHIGAN

Urologists Observe Anniversary.—The Detroit branch of the American Urological Association celebrated its twenty-fifth anniversary October 12. The fifty-one members present inscribed their names on a plaque to be forwarded to Dr. Frederick W. Robbins, formerly of Detroit and now of Pasadena, Calif., who in 1914 secured the charter from the American Urological Association.

MINNESOTA

Pilgrimage in Honor of Doctors Mayo.—In response to the request of many members, the council of the Minnesota State Medical Association sponsored a memorial pilgrimage to Rochester October 27 to pay tribute to Drs. William J. and Charles H. Mayo. Every member of the association was invited to participate in the ceremonies at Plummer Hall in the Mayo Clinic and at Oakwood Cemetery. With Dr. George A. Earl, St. Paul, president of the state medical association, presiding, at the memorial meeting in Plummer Hall Dr. Edward L. Tuohy, Duluth, gave the address entitled "An Expression from the Medical Profession of Minnesota." There followed a procession to the cemetery.

Society News.—The Minnesota Pathological Society was addressed October 12 by Dr. George H. Whipple, Rochester, N. Y., on "Production, Utilization and Significance of Blood Proteins."—Dr. Perrin H. Long, Baltimore, delivered a Mayo Foundation lecture October 10 in Rochester on "Experimental and Clinical Use of Sulfapyridine and Its Sodium Derivative in Treatment of Pneumococcal Infections."—At the seventy-first annual meeting of the Wabasha County Medical Society in Lake City October 5 Dr. Bertram J. Medisema, Rochester, on "Tetanus and Its Prevention"; Robert A. Glabe, Plainview, "Surgical Drainage of the Abdomen," and William E. Bannen, La Crosse, Wis., "Urologic Pathologic Museum."—Dr. Robert M. Burns, St. Paul, discussed "Accidents in Homes and Industries" before the Washington County Medical Society recently.

NEW HAMPSHIRE

Restrict Sale of Vitamin Concentrates.—The state board of health has given notice to "cut-rate stores, department stores, groceries, etc.," that sales of vitamin concentrates will render them liable to prosecution. These drugs fall in the category of potent drugs as defined by law, and hence their sale by other than drugstores is deemed a violation. The concentrates are commonly in the form of small capsules, the contents of which are usually less than 60 minims (4 cc.).

NEW JERSEY

Society News.—Dr. Norman H. Plummer, New York, addressed the Morris County Medical Society, Greystone Park, Morris Plains, October 19 on "Treatment of Pneumonia."—Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will address the Essex County Medical Society, Newark, November 9 on "American Medicine and the National Government."

NEW YORK

Society News.—Dr. Henricus J. Stander, New York, addressed the Medical Society of the County of Albany October 18 on "General Considerations of the Toxemias of Pregnancy."—Dr. William C. Clarke, Cornwall Bridge, Conn., addressed the Dutchess County Medical Society, Poughkeepsie, October 18 on "History of Surgery for the Past 200 Years, a day plan."—Dr. Milton A. Carvalho, Binghamton, addressed the Broome County Medical Society, Binghamton, October 10 on "Use of the Cystogram in Diagnosis of Placenta Praevia."—At a meeting of the Seneca County Medical Society at Willard October 11 a symposium on arthritis was presented by Drs. Louis M. Lockie, Roscoe D. Severance, Syracuse, and Thomas W. Maloney, Buffalo, Geneva.

Cancer Advisory Committee Appointed.—The state health commissioner, Dr. Edward S. Godfrey Jr., Albany, has appointed an advisory committee to assist the new division of cancer control in outlining policies and make available to it

the specialized knowledge of the members. The committee consists of Drs. Robert S. Cunningham, dean, Albany Medical College, Albany; James Ewing, director, Memorial Hospital, New York; Thomas P. Farmer, Syracuse, chairman of the council committee on public health and education, Medical Society of the State of New York; John J. Morton Jr., surgeon in chief, Strong Memorial Hospital, Rochester, and Francis Carter Wood, professor of cancer research, Columbia University College of Physicians and Surgeons. Dr. Morton L. Levin, New York, has been appointed assistant director of the new division, which has set up headquarters in the New York State Teachers' Association building, Albany. Formation of the division was announced in THE JOURNAL, October 21, page 1575.

New York City

Second Harvey Lecture.—Conrad A. Elvehjem, Ph.D., professor of agricultural chemistry, University of Wisconsin College of Agriculture, Madison, will deliver the second Harvey Society Lecture of the season at the New York Academy of Medicine November 16. Dr. Elvehjem will speak on "The Biological Significance of Nicotinic Acid."

Conference on Convalescent Care.—The New York Academy of Medicine is sponsoring a conference on convalescent care November 9-10. The program will include the following subjects: physiology and psychology of convalescence, relation of chronic disease to convalescence, results of recent research in nutrition with particular reference to the convalescent state, institutional care for various types of patients, psychosomatic factors of convalescence and the socio-economic aspects of convalescent care. In addition to the New York physicians who will present topics for discussion, the following guest speakers will participate: Drs. Oliver H. Perry Pepper and Isidor S. Ravdin, Philadelphia; William S. McCann, Rochester; Waldo E. Nelson, Cincinnati; Levellys F. Barker and G. Canby Robinson, Baltimore. A general meeting will be held Friday evening November 10 at which the speakers will be Dr. I. Ogden Woodruff, E. H. Lewinski Corwin, Ph.D., and Mr. Alfred H. Schoellkopf.

NORTH CAROLINA

Society Adopts Farm Security Program.—The Johnston County Medical Society at a meeting October 10 adopted the Farm Security Administration program for medical care for 1940. The supervisory board will be composed of the president and secretary of the society and one other member appointed each year by the two officers. It was also voted to place *Hygeia* in all county schools at the expense of the society.

Special Society Meeting.—The fifth annual meeting of the North Carolina Eye, Ear, Nose and Throat Society was held in Statesville September 21. The guest speakers were Drs. John J. Shea, Memphis, Tenn., on "Prevention of Complications of the Surgery of Tonsils and Adenoids" and "Management of Fractures of the Facial Bones" and James W. White, New York, "Relation of Ocular Muscles and Refraction." Dr. Albert G. Woodard, Goldsboro, was elected president; Dr. Milton B. Clayton, Statesville, vice president, and Dr. Milton R. Gibson, Raleigh, secretary, reelected.

NORTH DAKOTA

Semiannual Special Society Meeting.—Dr. Lawrence M. Randall, Rochester, Minn., was the guest speaker at the semi-annual meeting of the North Dakota Society of Obstetrics and Gynecology in Grand Forks October 21. His subject was "Some Clinical Phases of Endocrinology." Other speakers were Drs. James F. Hanna, Fargo, on "A Fifteen Year Review of Carcinoma of the Cervix Uteri at St. John's Hospital, Fargo"; John D. Graham, Devils Lake, "Medical Induction of Labor Near Term," and H. Robert Ransom, Grand Forks, "Pyelitis of Pregnancy."

OHIO

Annual Cardiovascular Institute.—The sixth annual cardiovascular institute under the auspices of the Heart Council of Greater Cincinnati, the West Virginia Heart Association and the Academy of Medicine of Cincinnati will be held November 14. The morning session will be at the Cincinnati General Hospital with Dr. William M. Sheppe, Wheeling, W. Va., speaking on "Syphilis of the Heart and Aorta" and Dr. Marion A. Blankenhorn, Cincinnati, "Hypertensive Heart Disease," and discussion by Dr. Timothy Leary, emeritus professor of pathology, bacteriology and medical jurisprudence, Tufts College Medical School, Boston. In the afternoon session at the University of Cincinnati College of Medicine Drs. Oscar B. Biern, Huntington, W. Va., and Johnson McGuire, Cincinnati,

will conduct round table discussions on cardiovascular syphilis. In the evening Dr. Leary will deliver the first Alfred Friedlander Lecture at the Academy of Medicine on "Pathology of Syphilis of the Cardiovascular System."

PENNSYLVANIA

Society News.—Dr. David M. Davis, Philadelphia, spoke before the Lycoming County Medical Society in Williamsport October 13 on urinary infections in females.—Dr. Russell Richardson, Philadelphia, discussed "Advances in the Treatment of Diabetes" before the Cambria County Medical Society, Johnstown, October 12.—Drs. Howard J. Thomas, Greensburg, and Robert C. Johnston, New Kensington, addressed the Westmoreland County Medical Society at the Mountain View Hotel October 25 on "Toxemias of Pregnancy" and "Surgical Headaches" respectively.—Dr. Stanford W. Mulholland, Philadelphia, addressed the Delaware County Medical Society, Chester, October 12 on "Hypertension's Challenge to Urology."

Philadelphia

Society News.—Drs. Michael Scott and Hershel C. Lennon, among others, addressed the Philadelphia Neurological Society October 27 on "Decerebrate Tonic Extensor Convulsions as a Sign of Occlusion of the Basilar Artery."—A panel discussion of "Practical Orthopedics for the Pediatricist" was presented at a meeting of the Philadelphia Pediatric Society October 10 by Drs. DeForest P. Willard, John A. Brooke, Jesse T. Nicholson and John P. Scott.

The "Blockley" Dinner.—The Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital, for many years known as "Blockley," will hold its fifty-third annual dinner at the Bellevue-Stratford Hotel December 5. Dr. William S. Middleton, dean, University of Wisconsin Medical School, Madison, will be the guest of honor and Dr. Arthur C. Morgan, president of the association, will preside. Members who do not receive notices are requested to send their correct addresses to the secretary, Dr. George Wilson, 133 South Thirty-Sixth Street, Philadelphia.

Woman's Hospital to Celebrate Merger.—A day of scientific meetings in celebration of the tenth anniversary of the merger of the Woman's Hospital of Philadelphia and West Philadelphia Hospital for Women will be held December 1 for all who have served as interns and residents at either institution. In the morning Dr. Margaret C. Sturgis will conduct an operative gynecologic clinic and Dr. Mary Hoskins Eashy a cardiac clinic, and Dr. Alberta Peltz will speak on "The Philadelphia Maternal Welfare Committee and Its Work." At the afternoon session the speakers will be Drs. Emily Lois Van Loon on "Bronchoscopy and Esophagoscopy as Related to the General Practitioner"; Emily P. Bacon, "Disorders in the Preschool Child," and Drs. Berta M. Meine and Ursula M. E. Hober, "Obstetric Service of the Woman's Hospital for the Past Ten Years," with demonstration. There will be a dinner in the evening at the Penn Athletic Club at which Dr. Mary R. H. Lewis, medical director of the hospital, will be toastmistress.

Pittsburgh

Society News.—At a meeting of the Allegheny County Medical Society October 17 the speakers were Drs. James W. Stevenson, Mount Lebanon, Pa., on "Bicornate Uterus Associated with Pregnancy"; Joseph W. Hampsey, "Masking of Clinical Picture of Acute Mastoiditis During the Administration of Sulfanilamide"; Alfred B. Sigmann, Bridgeville, "Clinical Study of Treatment, by Intra-Abdominal Lavage with 70 per Cent Alcohol, of Acute Suppurative Peritonitis (Appendicitis)," and Kenneth D. Eskey, "Sulfanilamide in Treatment of Gonorrhea."

VIRGINIA

Society News.—A symposium on pyloric stenosis was presented before the Mid-Tidewater Medical Society at Saluda recently by Drs. Nowell D. Nelms, Mathews; Russell von L. Buxton and William W. Falkner, Newport News; William Lowndes Peple and Charles R. Robins, Richmond.

Personal.—Dr. Leonard H. Denny has resigned as director of the department of public welfare of Portsmouth in order to return to service in the U. S. Navy, it is reported. Dr. Julian T. Miller, retired naval officer, has been appointed to succeed Dr. Denny.—Dr. William D. Tillson, director of the bureau of industrial hygiene, state department of health, since July 1936, has resigned to become medical director of the American Viscose Company, Parkersburg, W. Va.

State Medical Election.—Dr. Walter B. Martin, Norfolk, was named president-elect of the Medical Society of Virginia at the annual meeting in Richmond October 4 and Dr. Hugh

H. Trout, Roanoke, was installed as president. Vice presidents elected were Drs. Karl S. Blackwell, Richmond; Frank A. Farmer, Roanoke, and Philip W. Boyd, Winchester. Miss Agnes V. Edwards, Richmond, was reelected executive secretary-treasurer.

WASHINGTON

State Obstetric Meeting.—Dr. William M. Wilson, Portland, Ore., was the guest speaker at the annual meeting of the Washington State Obstetrical Society in Everett October 7. Dr. Wilson summarized discussions at the morning sessions and delivered two addresses, one at the afternoon session on "Experience with the Newer Endocrine Products" and another at the evening session on "Treatment of Pruritus Vulvae."

Society News.—Dr. Arthur E. Lien, Spokane, addressed the Spokane County Medical Society, Spokane, October 12 on "Nutrition and Its Relation to the Public Health."—The King County Medical Society was addressed October 16 by Drs. David Metheny on "Carcinoma of the Stomach" and Otis F. Lamson, Seattle, "Multiple Primary Carcinoma." Dr. Frank J. Heck, Rochester, Minn., addressed the society October 25 on "Practical Aspects of the Treatment of Anemia." A motion picture was shown on "The Adequate Neurological Examination" by Drs. Laurence Selling and Roger H. Keane, Portland, Ore.

WISCONSIN

Personal.—Dr. Virginia Small, formerly of Nashville, Tenn., has been appointed staff physician of the bureau of maternal and child health of the state board of health.

Changes in State Medical Board.—Dr. Robert E. Flynn, La Crosse, was appointed to the State Board of Medical Examiners by Governor Heil September 13. He succeeds Dr. Cornelius H. Cremer, Cashton. At a recent meeting in Milwaukee Dr. George R. Reay, La Crosse, was elected president of the board and E. C. Murphy, D.O., Eau Claire, was elected secretary.

Society News.—Drs. Ethel C. Dunham of the Children's Bureau, Washington, D. C., and Wyman C. C. Cole, Detroit, addressed the Milwaukee Pediatric Society October 11 on "Organization of the Pediatric and Obstetric Groups in a Campaign to Reduce Neonatal Mortality" and "Cyanosis of the Newborn" respectively.—Dr. Jay Arthur Myers, Minneapolis, addressed the Medical Society of Milwaukee County, Milwaukee, October 13 on "Controlling Tuberculosis in a Community." The meeting was a memorial to the late Dr. Hoyt E. Dearholt, for many years secretary of the Wisconsin Antituberculosis Association. Dr. Gilbert E. Seaman, Winnebago, gave an address on Dr. Dearholt's contributions to medicine and tuberculosis.

PHILIPPINE ISLANDS

University News.—Dr. Antonio G. Sison, dean of the College of Medicine, University of the Philippines, Manila, has been appointed director of the Philippine General Hospital also. The work of the hospital will be coordinated with that of the various units of the medical school, according to the *Journal of the Philippine Islands Medical Association*. President Quezon also authorized the establishment of a graduate school in the medical college in accordance with provisions of a law appropriating money for the purpose.

GENERAL

Ophthalmic Board to Hold One Written Examination.—The American Board of Ophthalmology announces that only one written examination will be held in 1940. This will be in various cities throughout the country March 2. All applications for this examination must be received before January 1 and all applicants must pass a satisfactory written examination before being admitted to the oral examination. Candidates planning to take the next oral examination, which will be in New York June 8-10, 1940, must file their case reports before March 1. The date of the fall examination will be announced later. For application blanks write at once to the secretary of the board, Dr. John Green, 6830 Waterman Avenue, St. Louis.

Medical Fellowships Available.—Fellowships in the medical sciences administered by the medical fellowship board of the National Research Council will be available for the year beginning July 1, 1940. These fellowships are open to citizens of the United States or Canada who have a Ph.D. or an M.D. degree and are intended for recent graduates rather than for persons already established professionally. The fellows will

be appointed at a meeting to be held about March 1 and applications must be filed on or before January 1. For further information address the Secretary, Medical Fellowship Board, National Research Council, 2101 Constitution Avenue, Washington, D. C. Dr. Alfred Blalock, Nashville, Tenn., and Homer W. Smith, D.Sc., New York, have been appointed members of the board.

Ohio Valley Allergists' Meeting.—The Ohio Valley Allergy Society held a meeting in Cincinnati October 28-29. Following a general discussion of "Potassium Chloride Therapy in Allergic Diseases," the speakers were:

Dr. Jonathan Forman, Columbus, Histamine Therapy in Allergic Diseases.

Dr. John H. Mitchell, Columbus, Emphysema—The Importance of the Excursions of the Diaphragm in Estimating Prognosis—Breathing Exercises.

Dr. George E. Rockwell, Cincinnati, Present Status of Tetanus Toxoid—Advisability of Its Use in Immunizing Horse Serum Sensitive Individuals.

Dr. Armand E. Cohen, Louisville, Ky., The Asthma Syndrome Due to Heart Disease.

Dr. Caryle B. Bohner, Indianapolis, Aspirin-Sensitive Asthmatics.

Special Society Elections.—Dr. Waller S. Leathers, Nashville, Tenn., was chosen president-elect of the American Public Health Association at the annual meeting in Pittsburgh October 16-20, and Dr. Edward S. Godfrey Jr., state health officer of New York, Albany, was installed as president. Vice presidents elected were Miss Elizabeth L. Smellie, R.N., chief superintendent of the Victorian Order of Nurses for Canada, Ottawa, Ont.; Dr. Domingo L. Ramos, Fabrica, P. I., and Dr. Wilton L. Halverson, Pasadena, Calif. The 1940 convention will be held in Detroit.—Dr. Everts A. Graham, St. Louis, was chosen president-elect of the American College of Surgeons at its annual session in Philadelphia October 19. Drs. Oliver S. Waugh, Winnipeg, Man., and Albert O. Singleton, Galveston, Texas, were elected vice presidents and Dr. George P. Müller, Philadelphia, was installed as president.

European Journals and the War.—The American Documentation Institute requests that subscribers to European chemical or other scientific journals who do not receive their copies report the matter promptly. The cultural relations committee of the institute hopes to be able to surmount such war obstacles as interrupted transportation, embargoes and censorship, which seriously affected the progress of research during the last war. It is hoped that the principle will be established that materials of research having no relation to war shall continue to pass freely, regardless of the countries of origin or destination. Reports with full details of where subscription was placed and name and address of subscriber, volume, date and number of the last issue received should be addressed to the American Documentation Institute, Bibliofilm Service, U. S. Department of Agriculture Library, Washington, D. C.

Southwestern Medical Association.—The twenty-fifth anniversary postgraduate conference of the Southwestern Medical Association will be held at the Hotel Cortez, El Paso, Texas, November 9-11. The program will consist of general assemblies, clinical and pathologic conferences, motion picture demonstrations and round table luncheons. The speakers will be:

Dr. Fred H. Albee, New York, orthopedic surgery.

Dr. Marye Y. Dabney, Birmingham, gynecology.

Dr. Leo Eloesser, San Francisco, surgery.

Dr. Samuel D. Ingham, Los Angeles, neurology.

Dr. Julius Lempert, New York, otology.

Dr. Charles F. McCuskey, Glendale, Calif., anesthesia.

Dr. Louis H. Newburgh, Ann Arbor, Mich., dietetics.

Dr. Henry M. Winans, Dallas, Texas, medicine.

A special feature of the meeting will be the presentation of a "Medical March of Time" by charter members of the association.

Dana Medal Awarded to Dr. Ellett.—The Leslie Dana Medal, awarded annually by the St. Louis Society for the Blind for "outstanding achievements in the prevention of blindness and the conservation of vision," was presented to Dr. Edward C. Ellett, Memphis, Tenn., at a dinner in St. Louis October 14. The presentation was to be made by Dr. Edward Jackson, Denver, first recipient of the medal in 1925, and another speaker was Mr. Lewis H. Carris, New York, general director of the National Society for the Prevention of Blindness, which cooperates in the selection of the recipient. Dr. Ellett, who is 69 years old, has practiced ophthalmology in Memphis since 1893 and was professor of diseases of the eye at the University of Tennessee College of Medicine from 1906 to 1922. He is a former president of the American Academy of Ophthalmology and Otolaryngology and of the American Ophthalmological Society and chairman of the Section on Ophthalmology of the American Medical Association.

A Healthier Nation

It is interesting that the annual report of the Ministry of Health, which of course was compiled before the outbreak of the war, shows that as we enter a period of destruction the health of the nation was never so good. The average weight of school children at the age of 12 has increased by 3 pounds and the average height by half an inch compared with ten years ago. The same tendency was shown in the medical examination of the conscripts, of whom nearly 83 per cent passed as grade 1. The death rate has again fallen and is now 8.5 per thousand of population, the lowest on record, just half what it was in 1901. Infant mortality has a new low record of 53 per thousand births, little more than one third of what it was at the beginning of the century. Maternal mortality in 1938 was less than 3 per thousand births, while only five years ago it was 4.4. The deaths from tuberculosis were again the lowest on record, being only half the number in 1911. But there has been a rise in the cancer mortality, the deaths numbering 68,605, which was 1,600 more than in the previous year.

Great progress has been made in the control of infectious diseases. Environmental diseases, such as cholera, typhus and plague, have almost entirely disappeared and the cases of typhoid have been substantially reduced. But the position is not so satisfactory with regard to diphtheria, of which the number of cases fluctuates from year to year without showing any general decline. There are about 3,000 deaths from typhoid every year. There has been no material decrease in the incidence of influenza, measles and whooping cough, but the death rate from these diseases has considerably declined. Comparison of the deaths per million of population for 1938 with the average for the decade 1921-1930 shows influenza 118 against 369, measles forty against 109, whooping cough twenty-seven against 114. In 1938 only eighteen cases of smallpox were notified, from which there were three deaths, the first since 1934. An exceptionally large number of cases of poliomyelitis, 1,489, were notified, almost twice those of the previous year.

Women Physicians in the Army

Following representations by the British Medical Association, a scheme has been authorized for the employment of women physicians with the army medical services in the war. They will be eligible for employment either as civilian medical practitioners or medical officers attached to the army medical corps with a military status. Civilian medical practitioners will be engaged under the same conditions and rates of remuneration as male practitioners. For the army medical corps they will first be accepted as medical officers with the relative rank of lieutenant but without a commission. They will receive advancement in relative rank as for the medical corps in war. They will wear a uniform to be decided on and will receive the same pay and allowances as for officers of the corps, except that their rations will be four fifths of those given to males (the accepted principle of all women personnel in the army).

Ambulance Trains Under Construction

The British railways are engaged in the construction of a number of ambulance trains for use both at home and overseas. Work has already been completed on several trains and, to enable more to be brought into service rapidly, work on different sections has been entrusted to seven railway work-

shops throughout the country. Each train is fully equipped with cars for traveling staffs of nurses, physicians, kitchens and wards. Casualty evacuation trains have also been built for use in the event of air raids, in order to assist in the distribution of injured civilians throughout the country. The fitting up of the trains includes electric lighting and steam heating and many devices to ensure the comfort of patients.

The Danger of Traction on the Scalp in Placenta Praevia

In 1925 J. A. Willett introduced a method of treating placenta praevia by traction on the fetal scalp with a forceps which he devised. This was applied to the scalp with a wide bite and traction was made by attaching a weight not exceeding 2 pounds. In Great Britain Willett's forceps has been extensively used. At the Section of Obstetrics and Gynecology of the Royal Society of Medicine, Prof. F. J. Browne stated that in a series of 3,103 cases of placenta praevia which he had collected and analyzed from the reports of eleven teaching hospitals it was used in 252 with a maternal mortality of 3.5 per cent and a fetal mortality of 46.4 per cent. The advantages claimed for the forceps are that (1) it can be applied when the os admits only one finger and therefore is too small to allow a foot to be brought down; (2) little internal manipulation is necessary; (3) the fetus is spared the dangers of breach delivery and the fetal mortality is therefore lower than after version. The average fetal mortality under all methods of treatment in this series was 54.2 per cent, so that there seems some justification for the last claim. But Browne has recently had two cases in which the use of the forceps was followed by *Bacillus welchii* infection of mother and fetus.

In the first case a secundipara aged 32 was admitted after losing about half a cupful of blood. She was thirty-two weeks pregnant. The position was left occipito-anterior high above the pelvic brim. A tentative diagnosis of placenta praevia was made and she was treated expectantly, but bleeding recurred three and eight days later and she was examined under anesthesia. The cervix admitted one finger and the placenta was felt to extend to the internal os. The membranes were ruptured and Willett's forceps was applied with a weight of 1½ pounds attached. Two days later labor pains had not begun, the temperature was 102 F. and there was a foul smelling discharge but no further bleeding. Pains began next day, when the temperature was 103 and the pulse 150. A dead fetus was born. It and the placenta were putrid. The mother's condition was so bad that a transfusion was done and B. *welchii* serum was given. Next day crepitations were felt in the abdominal wall and she died on the following morning. The necropsy showed gas bubbles in the rectus muscle and the blood vessels.

The second patient was a primigravida aged 28, admitted for bleeding of one week's duration. She was eight days overdue and the vertex was not engaged. She was treated expectantly, but as slight bleeding continued she was examined under anesthesia after nine days. The os admitted one finger with difficulty and the edge of the placenta was felt 1½ inches above the internal os. The membranes were ruptured and Willett's forceps was applied. Weak pains began and after nine hours the forceps came off spontaneously. Labor progressed slowly and after four days a putrid fetus was born. B. *welchii* serum was given intramuscularly as a prophylactic. The mother recovered. Cultures from the cervix showed B. *welchii*, numerous colon bacilli and a few fecal streptococci. Cultures from the fetal spleen grew B. *welchii*.

Browne pointed out that in applying Willett's forceps a more or less lacerated wound of the fetal scalp is necessarily made. The weight enables the fetal head to compress the placenta, but this compression arrests both the maternal and the fetal

circulation of the placenta, which is liable to kill the fetus and produces ideal conditions for infection by the Welch bacillus—a ragged wound in dead tissues. If the bacillus is present in the vagina or gains access to it, infection and gas gangrene are likely. It has been shown by Hill, of Melbourne, that this bacillus is widely distributed. He found it in the floor dust of labor wards and on the hands of medical attendants after washing and drying. Browne concluded that Willett's forceps should have no place in the treatment of placenta praevia.

Polypeptides in General Medicine and Psychiatry

Laignel-Lavastine revived the history of polypeptides before the Academy of Medicine by investigating the comparative value of polypeptidemia in blood urea, both in general practice and in psychiatry. Between 1928 and 1934 polypeptides were an object of infatuation among investigators, who now are somewhat disappointed, perhaps because they expected too much. According to Laignel-Lavastine and his collaborator Duguet, loss of interest in polypeptides is hardly reasonable. The sequence of chemical disintegrations which carries albumin to the urea includes polypeptides, intermediate between peptones and the amino acids. The chemical entity of these polypeptides is far from being precisely known. Polypeptides are defined by their precipitations induced by means of trichloroacetate and phosphotungstic acid, and their quite delicate dosage is based on these reactions. Goiffon and Spacey proposed a simpler and precise, though indirect, method, namely measuring the tyrosine content of the blood polypeptides. This is, in fact, quite regular in polypeptides though Fischer obtained some synthetically which did not contain any.

Pierre Duval draws from the dosage with polypeptides prognostications of interest to surgeons, namely that in those with extensive burns and in numerous cancer patients polypeptidemia is elevated.

In general medicine, Fiessinger has shown that hypopolypeptidemia, or at least an increased deamination index, is always high in hepatic insufficiency. A study of sixty cases (forty from the general practice, twenty from psychiatry) indicated to Laignel-Lavastine the same increase of the rate of polypeptidemia in hepatic cases but accompanied with a low azotemia rate. In mental cases, however, the polypeptidemia and azotemia rate is higher than the normal rate. This hyperpolypeptidemia is especially noticeable in senile dementia, confusion amentia, mania and alcoholism; diseases of patients of this class as a rule are accompanied with hepatic insufficiency. Whenever hyperpolypeptidemia is marked (tyrosine index of more than 100 mg.), prognosis is grave. On the other hand, polypeptidemia can shed light on the nature of certain pronounced azotemias (2 Gm. or more). If the polypeptidemia rate is moderately high, azotemia is often transitory and indicates merely renal lesions in their final stage. Claude likewise studied the variations of the polypeptide rate in the cerebrospinal fluid in the course of dementia paralytica and other mental conditions. Generally in catatonia not due to lesions the polypeptidemia rate is variable and does not suggest parallelism with the condition of the liver. In alcoholic psychosis it varies according to the organic condition of the patients. Normal in chronic alcoholic patients, it as well as the deamination index increases in acute or subacute cases. In dementia paralytica the polypeptides of the spinal fluid are probably increased by a disorder of nitrogen metabolism in consequence of brain modifications. No valid diagnostic or prognostic indications can be deduced from these investigations, at least in the field of mental diseases.

Cancerigenic Effect of Leprous Tissue

Professor Peyron, in collaboration with Sister Marie Suzanne, an investigator of leprosy, took from a leper of the mixed type ($N^1 L^2$) portions of a leproma of the jaw and kept it for fifty days in distilled water, where it underwent little change. On the fiftieth day a large quantity of Hansen's bacilli were found giving clear histologic proof of the leprous nature of the tumor. These leprous portions were mixed with an emulsion and injected into the scrotum of four adult rats and into the axillary and inguinal regions of three adult female rats. The female rats manifested no other reaction outside the common reabsorption granuloma. Two of the male rats developed a perceptible tumor in the third month. The first rat had an enormous scrotal tumor encroaching on the abdomen and a pleural metastatic swelling 2.5 cm. in length. The tumor presented all the traits of malignant tumors of the interstitial cells together with significant indications of dedifferentiation, in keeping with its malignant nature manifested by general signs of carcinomatous intoxication. In the second rat, killed before the other, the tumor was still benign but histologically all the more characteristic. No doubt can exist on the causal relation between the injection of leprous tissue and the appearance of the tumors. Spontaneous tumors in the interstitial glands of the testicles are rare. In the large collection of the Croker Institute and among the large number of rat tumors none have been found. Hence Peyron's leprous tissue products are of great interest. They could have been caused only by the bacillus itself or the products of the autolysis of the leproma. Neither of these hypotheses can be considered satisfactory in our present state of knowledge of experimental carcinoma. Nevertheless one can invoke in favor of the former assumption observations of Jensen's sarcoma, the appearance of which was likewise provoked by the injection of acid-resisting bacilli derived from a pseudotuberculosis of the intestine of an ox.

Radiotherapy in Uterocervical Carcinomas

It seems that uterocervical carcinomas are slightly on the increase. At any rate they occupy an important place in the deaths from cancer. Last June at the meeting of the Société de gynécologie obstétrique de Paris Dr. Simone Lacore Laborde set forth the results obtained by radiotherapy in cervical cancers at the Cancer Institute of the Faculty of Medicine of Paris. The classification adopted by the speaker is that of the subcommittee on cancer of the League of Nations and is divided into four stages. In the first stage, lesions are strictly confined to the cervix. In the second stage the parametrium is infiltrated. This stage includes the cancers at the upper part of the vagina. In the third stage, cancerous growth has reached the pelvic region or, rather, the vagina as far as the lower area. Isolated metastases may also be noted. In the fourth stage the cancer infiltration extends more or less to the neighboring organs, the bladder or rectum or it spreads to a greater distance. In the ten years from 1921 to 1932, 813 cervical carcinomas in the four stages were observed at the Institute of Cancer and 592 were treated: forty in the first stage, ninety-two in the second, 284 in the third and 176 in the fourth. Of the 592 patients, 384 were alive and without recidivation at the end of five years, 384 had died in the course of the five years and six had had a recurrence. One hundred and sixty-seven were living and without recidivation after five years. The proportion of cures during the five years varied according to the years between 12 and 37.9 per cent, the average being 28.2 per cent. There was the same difference according to the stages: fifty-seven, or 5 per cent, in the first stage; forty-eight, or 9 per cent, in the second; thirty-one, or 6 per cent, in the third, and only five in the fourth. The therapy employed was based on the combined use of radium and roentgen rays. Radium therapy was performed by means of tubes containing 10 mg. of radium with a filtration equivalent

lent to 1 mm. of platinum. For the roentgen therapy, high voltage was used with a 300, 400 and even 500 kilovolt pressure. Massive irradiation was refrained from because it induced a general shock without yielding better results. Teleradium therapy by means of an apparatus containing 5 Gm. of radium and permitting irradiations at 20 cm. from the level of the skin did not prove superior to classic methods. Technics of irradiation seem to commend themselves in preference to excision. According to Heyman (1927), surgery's record for cures is only 18 per cent on the average. Besides, one must consider the operative risks (from 7 to 9 per cent), whereas the mortality due to roentgen rays does not exceed 3 per cent.

BERLIN

(From Our Regular Correspondent)

Sept. 10, 1939.

The Abuse of Hypnotics

The public health department of the reich has just published information regarding the use of sleep inducing drugs. It has instituted an inquiry in about 250 clinics, hospitals and centers for mental diseases to secure exhaustive data of the extent of the use of these drugs. It plans to propose that all such drugs as well as pain allaying preparations containing barbituric acid derivatives be dispensed only on medical certification. The greatest attention has officially been given to this ever present problem and the impression may have been created that the use of these drugs has declined. However, the information given to the public health department by relatives of sleeping drug addicts, by physicians, by druggists, by medical district associations, by the police, by health bureaus and by administrative authorities has been so copious that the conclusion is inevitable that the use of these drugs is on the increase. Observations have been made that opium addicts, in consequence of the enforcement of antinarcotic measures, now resort to hypnotics, which they can easily obtain since a medical prescription is not necessary. It is also said that the combined action of alcohol and barbituric acid is mutually intensifying. The public health department has information indicating that hypnotics not requiring prescriptions are increasingly ordered in large quantities by individual users. The use of hypnotics also gives rise to a diagnostic problem. Professor Bonhoeffer, psychiatrist in Berlin, reported that within the last decade wrong diagnoses, previously unknown, of brain tumors had become more numerous, owing to the fact that persons with chronic barbituric acid intoxication had concealed the use. He mentioned among deceptive symptoms slowly increasing stupor, speech disturbances, nystagmus and loss of abdominal reflexes. Professor Pohlisch, psychiatrist in Bonn, reported the case of a university professor who was dismissed because of alleged hereditary epilepsy and for whom sterilization was recommended. It was then discovered that the chronic use of hypnotics was the cause of his condition.

Efforts to Use Workers Who Are Chronically Ill

In view of the great demand for workers in Germany it is especially important to examine the possibilities of economic adjustment for those with chronic ailments. Two series of lectures of a postgraduate nature were recently given at the Berlin Academy for Physicians, on the significance of primary symptoms for timely therapy and prophylaxis, especially with reference to workers, and on economic adaptation of workers with chronic ailments. The lectures were intended to supply information to factory physicians and assistant physicians in charge of departments and practicing physicians interested in these questions. Explanations by state secretary Syrup of the economic needs in the four year plan formed the basis of all the lectures. In Germany, not counting Bohemia and Moravia, 40,000,000 persons are employed in industry. In 1936 lack of skilled laborers became noticeable. Reserves of male workers

are no longer available. Replacement of men with women brings with it dangers to their health. It is essential for public welfare that workers be adjusted to the jobs by which they can maintain themselves. Responsibility for this rests largely on physicians, especially factory physicians. The factory physician should inform himself on how workers live, their family conditions and so on, all of which are important factors affecting efficiency. Treatment of sick workers is not his function; however, he may represent the patient's physician in supervising directions given by him. Observations of slight, scarcely measurable pathologic changes, of scarcely noticeable decrease in efficiency and of early recognition of harmful symptoms might constitute valuable information for the maintenance of health of workers. By observing health measures in a factory and the habits of individual workers the factory physician may, like a seismograph, observe every change in the frequency of diseases and accidents and obviate or relieve them by determining the causative factors. He will have to work in close cooperation with the management. Observations of large groups at work and the evaluation of extensive observational data representing an accumulation of more than 350,000 cases may open up a new field of medical territory. The scarcity of qualified labor has made necessary the employment of those physically below par and involves increased obligations for the cooperating and supervising factory physicians.

ECONOMIC EMPLOYMENT

The second series of lectures, on the economic employment of persons with chronic ailments, was supplementary to the first. The care of such persons constitutes a heavy drain on social insurance reserves. To what extent persons with chronic ailments are dependent on social insurance has not been determined statistically. However, the statistics furnished by individual sick funds and state insurance companies in the provinces offer some information. Among those chronically ill are persons with tuberculosis, cancer, cardiac and vasomotor diseases, diabetes, and those with gastric and intestinal disturbances. It is of little value for such persons to be declared by the physician in charge as fit or unfit for work. At present fitness for work is determined by the social insurance physicians, who work in close cooperation with the public health office, the labor department and the practicing physician in the detection of public diseases. The practical operation of such cooperative services is discernible, for example, in the clinic established in Berlin to determine diabetes. At present, 14,300 diabetic persons, including 118 married couples, are served there.

CARE OF EMPLOYEES

Through arrangements, workers who are not entirely unfit physically can do satisfactory work connected with the soil or excavation. Factory workers with circulatory disorders in charge of machines with rotating belts can easily receive injury, though the work is not difficult. The factory physician should be consulted in determining the speed with which work of this kind should be done. Rational arrangement may enable the injured and even persons with amputated limbs to work. In the case of women, often it is not the heavy work, but certain harmful effects like constant vibrations and injuries caused by continued foot manipulations that are significant. These explanations, elaborated by detailed discussions in lectures, show how effort is made to utilize the working ability of every one by exhausting all possible medical knowledge.

Water Requirements of Workers Under Heat Pressure

Dr. Hebestreit expressed himself in the new periodical *Health Guidance of the German People* on the water requirements of workers under heat pressure. Workers who toil under conditions of great heat lose on an average more than a gallon of water during a working day of eight hours. This loss should

be compensated by drinking during work. However, every excess is to be avoided in order not to burden the circulation and to prevent gastric troubles. Above all, beverages taken should not be too hot or too cold, but lukewarm or of the temperature of the room. Beer and mineral waters are not suitable. Coffee should be drunk with the addition of milk. In the stoker rooms of ships, gruel made for example of oats and rice has proved its worth. It slakes the thirst well and supplies the body with salts to replace those lost in perspiration. For that reason gruel is to be recommended to workers under similar heat conditions. In place of black tea, which has no appetizing taste at room temperature, teas of native growth are recommended, such as teas made from blackberry and strawberry leaves or from peppermint. To supply the body with easily absorbable food values during great physical exertion, sugar can be added to the tea; to supplement loss of salts, from 2 to 3 Gm. of salt per quart of beverage can be added without noticeably impairing its taste.

Marriages

PETER A. N. PASTORE, Bluefield, W. Va., to Miss Julia Anna Rourke of Prides Crossing, Mass., at Rochester, Minn., September 14.

CHARLES WESTON WARREN, Upperville, Va., to Miss Geraldine Estelle Mitchell of Winston Salem, N. C., recently.

WILLIAM GREGORY THALMANN JR., Philadelphia, to Miss Sara Carpenter Klopp of Rosemont, Pa., September 30.

FERDINAND E. CHATARD IV, Baltimore, to Miss Constance Bentley Lyon of Purcellville, Va., September 9.

NEEDHAM BRYANT BATEMAN to Miss Florence Estele Stevenson, both of Atlanta, Ga., September 4.

JAMES A. BRADLEY to Mrs. Evelyn Neuling, both of St. Petersburg, Fla., in Tampa, October 1.

FRANKLIN LEROY WILSON, Montreat, N. C., to Miss Eleanor D. Garrett of Miami, Fla., September 7.

ROBERT LEE SANDERS, Columbia, S. C., to Miss Helen Jessa McDowell of Charleston, September 23.

CHARLES E. CONNER, Wenatchee, Wash., to Miss Marthe Irwin of Colorado Springs, July 15.

JOSIAH HARRIS SMITH, Selma, Ala., to Mrs. Gladys Buckmaster Wire at Cincinnati in August.

PERCY F. GUY, Seattle, to Dr. MAY A. BORQUIST of Honolulu, Hawaii, in Portland, July 15.

IRVING W. SALOWITZ, to Miss Dorcas Maric Crook, both of Plymouth, Ill., September 24.

JOE M. VANHAY, New York, to Miss Helen Spangler of Greenville, N. C., September 6.

LEON BLUM, Far Rockaway, N. Y., to Miss Janette Goldstein of Atlanta, Ga., August 8.

J. ELLIOTT ROYER, Oakland, Calif., to Miss Helen Hay of Pasadena, Calif., September 28.

PAUL B. WILSON to Miss Esther Elizabeth Roberts, both of Philadelphia, September 25.

EARL STOUGH TAYLOR to Miss Virginia Hanson, both of New York, September 23.

SIDNEY F. YUGEND, Sigourney, Iowa, to Miss Bertine Hooper of Hartford, September 8.

HARRY D. TRIPP to Miss Elizabeth Kopp, both of Logansport, Ind., September 30.

FREDERICK R. MINNICH to Miss Katherine Callhoun, both of Atlanta, Ga., recently.

WALTER SHRINER, Elgin, Ill., to Miss Ruth Arline Shearer of Aurora, August 26.

WILLIAM S. COLE, Seattle, to Miss Catherine Rutledge of Burlington, August 5.

LEON E. POLLOCK to Miss Jean Berry, both of Spokane, Wash., August 13.

FRANCIS SAUER, Canton, Ohio, to Miss Irma Dotts at Carrollton, August 14.

JOHN B. DYNES to Miss Edna Bradbury, both of Boston, September 22.

Deaths

William Bricker Chamberlin @ Cleveland; Western Reserve University Medical Department, Cleveland, 1900; secretary of the Section on Laryngology, Otology and Rhinology of the American Medical Association from 1918 to 1922 and chairman from 1922 to 1923; clinical professor of otolaryngology at his alma mater and at various times associate clinical professor, assistant clinical professor, associate and instructor in otolaryngology; member, past president and vice president of the American Laryngological Association; member, past president and secretary-treasurer of the American Bronchoscopic Society; past president of the Cleveland Association for the Hard of Hearing and of the Cleveland Academy of Medicine; member of the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; on the staff of the University Hospitals of Cleveland; aged 65; died, September 5, in Cleveland Heights of coronary sclerosis and thrombosis.

Arthur Godfrey Fort @ Atlanta, Ga.; Atlanta College of Physicians and Surgeons, 1904; past president of the Medical Association of Georgia; member of the American Academy of Ophthalmology and Otolaryngology and the Southeastern Surgical Congress; fellow of the American College of Surgeons; instructor of ophthalmology at the Emory University School of Medicine, 1918-1924; commissioner of health of Irwin and Tifton counties in 1916; served at various times and in various capacities on the staffs of the Piedmont Sanitarium, Wesley Memorial Hospital, Georgia Baptist Hospital, Crawford W. Long Memorial Hospital and the Grady Hospital; aged 61; died, September 15, in the Emory Hospital of myocarditis and pulmonary edema.

Albert Bernard Yudelson @ Chicago; Northwestern University Medical School, Chicago, 1906; associate professor of medical jurisprudence and nervous and mental diseases at his alma mater; member of the Central Neuropsychiatric Association; past president of the Chicago Neurological Society; served during the World War; attending neurologist to the Cook County Hospital and the Wesley Hospital; aged 67; died, August 27, of coronary thrombosis.

John William McIntosh, Burnaby, B. C., Canada; University of Toronto Faculty of Medicine, 1894; formerly medical officer of health of Burnaby and Vancouver; served during the World War with the Canadian Army; from 1916 to 1920, was a member of the provincial legislature; past president of the Canadian Public Health Association; aged 68; died, August 12.

William Garretson Carhart, Fort Lyon, Colo.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; served during the World War; instructor of pathology and bacteriology at the University of Missouri, Columbia, from 1904 to 1907; on the staff of the Veterans Administration; aged 65; died, September 17, of coronary occlusion.

Bennett Sheldon Beach @ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staff of the New York Eye and Ear Infirmary; aged 77; died, September 13.

Thomas Edward Parker, Waterbury, Conn.; Yale University School of Medicine, New Haven, 1904; member of the Connecticut State Medical Society; served during the World War; on the staff of St. Mary's Hospital; aged 58; died, August 1, in the New Haven (Conn.) General Hospital of diabetes mellitus and pyelitis.

William A. Zellars, Shaker Heights, Ohio; College of Physicians and Surgeons, Baltimore, 1891; formerly president of the board of education of Freeport, postmaster and member of the county board of education; at one time president of the bank of Freeport; aged 73; died, August 11, in Cleveland of uremia.

David Ernst Matzke, Punxsutawney, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1925; member of the Medical Society of the State of Pennsylvania; served during the World War; on the staff of the Punxsutawney Hospital; aged 40; died in August of acute dilatation of the heart.

Roy George Pfozter @ Buffalo; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1924; associate in medicine, University of Buffalo School of Medicine; fellow of the American College of Physicians; on the staff of the Millard Fillmore Hospital; aged 46; was drowned, August 9.

Cooper Curtice, Beltsville, Md.; Columbian University Medical Department, Washington, D. C., 1888; formerly associated with the Bureau of Animal Industry, U. S. Department of Agriculture; was known for his researches on cattle tick fever; aged 83; died, August 8, of coronary occlusion.

Charles W. Bankes, Middleport, Pa.; College of Physicians and Surgeons, Baltimore, 1881; member of the Medical Society of the State of Pennsylvania; bank president; aged 82; on the associate staff of the Pottsville (Pa.) Hospital, where he died, August 27, of cerebral hemorrhage.

Paul Whiting Woodruff Ⓢ Chatfield, Minn.; State University of Iowa College of Medicine, Iowa City, 1933; formerly resident to the Chicago Lying-in Hospital and Dispensary; aged 34; died, August 16, in a hospital at Winona, Miss., of injuries received in an automobile accident.

John Joseph Shea, San Diego, Calif.; Harvard Medical School, Boston, 1897; member of the California Medical Association; at one time member of the board of health of Beverly, Mass.; aged 70; died, August 19, in the Mercy Hospital of hypertrophy of the prostate and uremia.

Charles A. Duffy Ⓢ Pittsburgh; Georgetown University School of Medicine, Washington, D. C., 1910; fellow of the American College of Surgeons; on the staff of the Southside Hospital; aged 52; died, August 26, in the Buffalo (N. Y.) General Hospital of coronary occlusion.

Walter Algeno Allen Ⓢ Hampstead, N. H.; Dartmouth Medical School, Hanover, 1893; served during the World War; for many years member of the school board and board of health; formerly state senator; aged 70; died, August 23, in the Benson Hospital, Haverhill, Mass.

Leone Franklin La Pierre, Norwich, Conn.; Yale University School of Medicine, New Haven, 1901; member of the Connecticut State Medical Society; for many years on the staff of the William W. Backus Hospital; aged 62; died, August 7, of cerebral hemorrhage.

Hiram Bachelder West, Los Angeles; Dartmouth Medical School, Hanover, N. H., 1900; member of the American Psychiatric Association; on the staff of the Veterans Administration Facility, West Los Angeles; aged 59; died, August 11, of coronary thrombosis.

Edgar Jonas Knapp, Rice Lake, Wis.; Harvard Medical School, Boston, 1892; member of the State Medical Society of Wisconsin; aged 72; died, August 29, in the Veterans Administration Facility, Fort Snelling, Minn., of carcinoma of the duodenum.

John Ludwig Loutfian, Coxsackie, N. Y.; Medico-Chirurgical College of Philadelphia, 1902; member of the Medical Society of the State of New York; village health officer; aged 64; died, August 5, in the Albany (N. Y.) City Hospital.

Caroline Le Monte Rolph Bassmann, Claremore, Okla.; Northwestern University Woman's Medical School, Chicago, 1897; member of the Oklahoma State Medical Association; aged 70; died, September 30, in St. John's Hospital, Tulsa.

Raymond Alexander Turnbull, Elmira, N. Y.; University of Buffalo School of Medicine, 1904; member of the Medical Society of the State of New York; served during the World War; aged 58; died, August 13, in St. Joseph's Hospital.

Edwin C. Bandy, Alabama City, Ala.; Medical College Montezuma University, Bessemer, 1898; member of the Medical Association of the State of Alabama; aged 78; died in September in Gadsden of extensive burns and bronchopneumonia.

Oliver Hines Finnical, Cadiz, Ohio; Starling Medical College, Columbus, 1895; member of the Ohio State Medical Association; aged 67; died, September 9, in the Ohio Valley General Hospital, Wheeling, of cerebral thrombosis.

Franklin J. Cushman Ⓢ Lansing, Mich.; Detroit College of Medicine and Surgery, 1921; member of the American Urological Association; served during the World War; aged 42; died, September 11, of bilateral renal calculus.

James Merlin Fitzgerald Ⓢ Chicago; Jenner Medical College, Chicago, 1908; professor of mental physiology at Bennett Medical College, 1903-1910; aged 69; died, August 16, in San Francisco of carcinoma of the bladder and liver.

Harper Leonidas Crow, Bossier, La.; University of Louisville (Ky.) Medical Department, 1913; served during the World War; aged 53; was killed, September 3, when the truck in which he was driving overturned.

Albert Earl Reed Ⓢ Larned, Kan.; Rush Medical College, Chicago, 1905; secretary of the Pawnee County Medical Society; medical director of the Larned City Hospital; aged 58; died, August 30, of coronary occlusion.

George T. Van Cleve, Malden, Mo.; University of Louisville (Ky.) Medical Department, 1879; member of the Missouri State Medical Association; aged 86; died, August 5, in the Baptist Hospital, Memphis, Tenn.

Fred Raines Morrow Ⓢ Fayetteville, Ark.; Memphis (Tenn.) Hospital Medical College, 1900; served during the World War; on the staff of the City Hospital; aged 68; died, August 15, of coronary embolism.

Frederick Ogle Roman, Washington, D. C.; National University Medical Department, Washington, 1894; member of the Medical Society of the District of Columbia; aged 73; died, August 12, of lymphatic leukemia.

Samuel T. Williams, Waynesburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1896; aged 70; died, August 4, in the Greene County Memorial Hospital of pulmonary edema following fracture of the femur.

Alfred Loomis Sawyer, Fort Fairfield, Maine; Medical School of Maine, Portland, 1907; member of the Maine Medical Association; served during the World War; aged 57; died, August 14, of acute pancreatitis.

Troy England Martin Ⓢ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1934; aged 29; on the staff of the Germantown Hospital, where he died, August 21, of streptococcal pneumonia.

James Edward Rudasill Ⓢ Markham, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; aged 67; died, August 2, in the Western State Hospital, Staunton, of hypertensive heart disease.

Elliott Benald Tobias, San Francisco; College of Physicians and Surgeons of San Francisco, 1921; member of the California Medical Association; aged 40; died, August 2, of coronary occlusion.

Paul Eskeberg, Miami, Fla.; Northwestern University Medical School, Chicago, 1938; member of the Florida Medical Association; aged 28; died, September 3, of chronic myelogenous leukemia.

Benjamin Franklin Hawk, West Palm Beach, Fla.; Columbus Medical College, 1891; aged 72; died, August 15, in the Veterans Administration Facility, Bay Pines, of carcinoma of the prostate.

Alfred Frederick Zittel, Buffalo; University of Buffalo School of Medicine, 1899; member of the Medical Society of the State of New York; aged 67; died, August 28, of carcinoma of the bladder.

Orville DeWitt Wescott, Walla Walla, Wash.; Rush Medical College, Chicago, 1904; on the staff of the Veterans Administration Facility; aged 68; died, August 29, of coronary thrombosis.

Paul Luttinger, New York; University and Bellevue Hospital Medical College, New York, 1911; member of the Medical Society of the State of New York; aged 54; died, August 11, of pneumonia.

George Lee Long, Fresno, Calif.; Hahnemann Medical College, San Francisco, 1886; formerly county health officer and county coroner; aged 81; died, August 12, of coronary occlusion.

John Henry Adams, Crockett, Calif.; College of Physicians and Surgeons of San Francisco, 1911; member of the California Medical Association; aged 51; died, August 16, in Oakland.

David Martin Levine, Detroit; Wayne University College of Medicine, Detroit, 1937; member of the Michigan State Medical Society; aged 28; died, August 7, of acute lymphatic leukemia.

Newton J. Boswell, Decatur, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1893; aged 66; died, September 8, of cerebral hemorrhage, arteriosclerosis and hypertension.

J. O. Bickham, Winchester, Ark.; Gate City Medical College, Dallas, Texas, 1903; aged 58; died, August 13, of myocarditis, acute dilatation of the heart, nephritis and hypertension.

Roy Lee Aiguier, Sulphur Springs, Texas; Southern Methodist University Medical Department, Dallas, 1914; served during the World War; aged 50; died, September 3, in Fort Worth.

James G. Robertson, Arrington, Tenn.; University of Tennessee Medical Department, Nashville, 1899; aged 77; died, August 21, in Cedar Hill, of carcinoma of the right side of the jaw.

Samuel A. Benson, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1896; aged 72; died, September 3, in the City Hospital of burns received when his home caught fire.

Thomas Jefferson Bouldin @ St. Johns, Ariz.; Atlanta College of Physicians and Surgeons, 1901; past president of the Apache County Medical Society; aged 61; died in September.

James Henry O'Connor, St. Helena, Calif.; Columbia University College of Physicians and Surgeons, New York, 1899; served during the World War; aged 66; died, August 1.

John Henry Witbeck, Cayuga, N. Y.; Bellevue Hospital Medical College, New York, 1888; for many years health officer; aged 74; died, August 2, of a ruptured gastric ulcer.

Nathaniel Massie McKitterick, Burlington, Iowa; Rush Medical College, Chicago, 1880; formerly member of the state board of health; aged 81; died, August 29, of angina pectoris.

Adelbert D. Bowen, West Lodi, Ohio; Toledo Medical College, 1885; aged 79; died, September 2, in the Mercy Hospital, Tiffin, following an operation for strangulated hernia.

Thad S. Up de Graff @ Pasadena, Calif.; Jefferson Medical College of Philadelphia, 1883; aged 74; died, August 2, in the Collis P. and Howard Huntington Memorial Hospital.

Norbert Vincent Mullin, Weymouth, Mass.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; aged 59; died, August 18, in the Weymouth Hospital.

Edward Plotkin, Nashville, Tenn.; College of Physicians and Surgeons, Memphis, 1909; aged 56; died, August 24, in the Nashville General Hospital of cerebral hemorrhage.

Frederick A. York, Navasota, Texas; University of Texas School of Medicine, Galveston, 1898; aged 65; died, August 22, in the Brazos Valley Sanitarium of paralytic ileus.

Robert Fred Zeiss @ New York; University of Texas School of Medicine, Galveston, 1916; member of the American Urological Association; aged 46; died, August 8.

Randolph D. Black, Cedar Grove, W. Va.; University of Nashville (Tenn.) Medical Department, 1903; aged 62; died, September 2, of carcinoma of the lumbar spine.

George William Lawler, Waukesha, Wis.; Milwaukee Medical College, 1908; aged 65; died, August 22, in the Waukesha Municipal Hospital of pneumonia.

Charles H. Davies, Kansas City, Kan.; Jefferson Medical College of Philadelphia, 1877; aged 86; died, September 16, of pernicious anemia and hypostatic pneumonia.

Frank J. Campbell, San Diego, Calif.; Chicago Medical College, 1890; aged 77; died, August 24, in the Mercy Hospital of cerebral hemorrhage and arteriosclerosis.

John H. T. Earhart, Westminster, Md.; University of Maryland School of Medicine, Baltimore, 1888; aged 77; died, September 10, of coronary thrombosis.

Howard Leon Sumner @ Asheville, N. C.; Jefferson Medical College of Philadelphia, 1926; county health officer; aged 37; died, August 16, of heart disease.

William Henry Bennett, Fitchburg, Mass.; New York Homeopathic Medical College and Hospital, 1889; aged 75; died, August 3, of arteriosclerosis.

Allice Grace Charlton Guequierre, Wayne, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1922; aged 45; died, August 6, of carcinoma.

Thomas Raymond Thorn, Los Angeles; University of Texas School of Medicine, Galveston, 1927; aged 35; was killed, August 13, in an airplane accident.

George B. Hunter, Syracuse, N. Y.; Baltimore University School of Medicine, 1897; aged 64; died, August 25, in the University Hospital of pneumonia.

James Frank Hufford, Elrama, Pa.; University of Pittsburgh School of Medicine, 1910; aged 58; died, August 26, of uremia and arteriosclerosis.

Smith L. Bates, Adrian, Mo.; Medical College of Ohio, Cincinnati, 1878; aged 87; died, August 24, in a hospital at Kansas City of pneumonia.

Frank Alonzo Dearborn, Nashua, N. H.; Missouri Medical College, St. Louis, 1884; aged 81; died, August 3, of arteriosclerosis and heart disease.

James Henry Burnett @ Kopperl, Texas; Atlanta (Ga.) Medical College, 1895; aged 67; died, August 22, of hypertension, nephritis and uremia.

Bureau of Investigation

THREE POSTAL FRAUD ORDERS

Durio Cosmetic Company

A CONTINUATION OF THE C. A. WILLIAMS FRAUD IS
DEBARRED FROM THE MAILS

In this department of THE JOURNAL for Feb. 11, 1939, there appeared a brief story about the closing of the mails to the C. A. Williams Company, of McKamie, Ark. The title was a trade name used by two Negroes, C. A. Williams, who was 70 years old and who founded the business in 1929, and Ples L. Lewis, who in 1936 acquired a controlling interest (93 per cent) from Williams.

The concern sold a line of nostrums through the mails for the alleged cure of gonorrhea, syphilis, pellagra, paralysis, delayed menstruation, leukorrhea, rheumatism, "lung trouble," and so on. The Post Office authorities showed that the two men who conducted this swindle bought their preparations in gallon bottles from a St. Louis drug firm and then rebottled them into smaller bottles as needed. As the nostrums were quite worthless as cures for conditions for which they were sold, a fraud order was issued Aug. 23, 1938, closing the mails to the C. A. Williams Medicine Company.

But this did not stop the fraud. Williams and Lewis changed the name of their company and continued to do business at the old stand. The "C. A. Williams Company" became "Durio Cosmetic Company" and the sale through the United States mails of worthless swindles for the alleged cure of such diseases as syphilis, gonorrhea and pellagra went on. As a result the Post Office Department on March 3, 1939, issued a supplemental fraud order closing the mails to the Durio Cosmetic Company.

The Stroopal Fraud

A FAKE CANCER "CURE" BOBS UP AGAIN

The Stroopal case presents another example of how some slippery individuals attempt to evade fraud orders debarring them from the use of the United States mails. As long ago as 1930 the Post Office Department declared the Stroopal business of Chicago to be a fraud and closed the mails to this concern. The principal, Alphonse P. Faupel, however, continued

his business in the United States by operating it from London, England. The Post Office authorities, therefore, have found it necessary to issue a supplementary fraud order covering the London address.

The Stroopal cancer cure fraud originated in Germany many years ago with a self-styled "Professor" Stroop. It consists of three powders to be taken at monthly intervals when the moon is new! To the city bred this in itself might appear to arouse suspicion. But there are many otherwise intelligent country people who are still convinced that a calf should be weaned and the potatoes planted at certain phases of the moon. The advertising of Stroopal was declared *verboten* in Germany some years ago and so the headquarters of the fraud were transferred to London, where a greater degree of *laissez faire* was permitted. A Chicago branch was opened and for nearly twenty years the American branch of the fraud was conducted

from that city with agencies in Centralia, Okla., and Seneca, Kan. Most of the American business was directed to Americans of German descent, for much of the advertising was printed in German script.

According to Gehe's Codex (January 1913) Stroopal was nothing more marvelous than the powdered leaves of water germander or wood garlic (*Teucrium scordium*). In August 1930 the Post Office Department issued a fraud order barring Stroopal from the United States mails. The department brought out at the time that in the exploitation of Stroopal medals and "certificates of merit" were featured in the advertising and the claim was made that the product had been awarded these medals and certificates at exhibitions at Antwerp, Brussels and Paris. They were all utter fakes! It was shown, too, that when the importation of Stroopal was barred as dangerous to the health of the people the stuff was for a while smuggled into this country as "metal cleaning powder."

The scheme, and the government's action against it, were dealt with in an article in this department of *THE JOURNAL* for Oct. 4, 1930, and the matter in a condensed form appears in the book "Nostrums and Quackery and Pseudo-Medicine," volume III, published by the American Medical Association. Now, in 1939, the fraud again engages the attention of the United States Post Office Department. The Faupel quack was still selling his stuff to such victims as he could get in the United States from his office in London, England. As a result the fraud order issued in 1930 was supplemented by another issued March 6, 1939, closing the United States mails to the Stroopal Company and to Alphonse P. Faupel, both of London. All postmasters authorized to dispatch letter mail to England have been notified to return all letters addressed to the Stroopal concern to the senders with the word "Fraudulent" stamped plainly on the envelop. Also postmasters are warned not to issue any postal money orders payable to the Stroopal concern.

A Maté Fakery

PEREZ-MATÉ COMPANY OF BROOKLYN DEBARRED
FROM THE MAILS

During the past few years attempts have been made to popularize in this country the South American beverage maté, also known as Paraguay tea. Yerba maté, while having a different flavor from that of the ordinary India or China teas of commerce, has the same physiologic effect. Like common tea it contains variable amounts of caffeine and tannin. To the average American palate maté seems to have a medicine-like taste and therefore it is not surprising that some of the promoters, finding it a poor seller as a beverage, endowed it with "patent medicine" qualities. As a pepper-up for weak men and frigid women it was apparently more of an economic success.

From Brooklyn one Arthur Koppel, using the trade style Perez-Maté Company, for about eight years put out maté under the names "Ola Maté," "Brazilian Maté" and "Para-Brazilian Maté." It was sold through the mails and the fraud order arm of the Post Office Department finally got around to it. According to the memorandum that Judge Vincent M. Miles, Solicitor for that department, sent to the Postmaster General, recommending the issuance of a fraud order, Koppel bought his Paraguay tea in bulk at 10½ cents a pound, repacked it and sold it for \$2 a pound. According to Koppel's advertising, said Solicitor Miles, all users of his brand of maté would "enjoy real health, he-man virility, pep and strength" and "weak men" who took it would have virile sex-power restored "almost overnight." Koppel also claimed that his maté would restore all persons using it to good health but he advised a Post Office inspector that he (Koppel) was unable to leave his house because of ill health!

Despite Koppel's claim that he had discontinued advertising his maté product, Solicitor Miles's memorandum stated that there was evidence that Koppel had recently sent literature on it to persons who inquired about a perfume that Koppel advertised under the name of the He-Mo Company. On March 21, 1939, the Postmaster General, acting on Judge Miles's recommendation, issued a fraud order against Koppel's Perez-Maté Company of Brooklyn and its officers and agents as such.

Correspondence

"DOG BITES AND RABIES"

To the Editor:—Your remarks on "Dog Bites and Rabies" (*THE JOURNAL*, October 7, p. 1434) is a fine example of how one mistake often leads to another.

Cabot in 1899 reported that he saved 91 per cent of the guinea pigs cauterized with nitric acid at the end of twenty-four hours. Rosenau more recently has reported practically 100 per cent of guinea pigs saved by prompt application of nitric acid. In my experience wounds treated with nitric acid heal satisfactorily, and I have never seen one become infected. I believe that the theory that the use of nitric acid causes the spread of infection is not borne out by clinical experience.

Cases of paralysis, some of which have ended fatally following the Pasteur treatment, have been reported in the literature. It should be pointed out that practically all veterinarians who treat rabies have discontinued the use of material prepared by the Pasteur method and are now using material prepared by the Semple method. Since they have so much more experience in treating rabies than do physicians, I believe that their experience should be given consideration. One is forced at least to bring out the fact that vaccine prepared by the Semple method is evidently safer, and the dosage can be more varied according to the clinical indications because one is using a killed rather than an attenuated virus.

L. B. GLOYNE, M.D., Kansas City, Kan.

From the Department of Preventive Medicine,
University of Kansas School of Medicine.

[COMMENT.—In *Queries and Minor Notes* (this issue, p. 1754) appears an additional discussion of paralysis following rabies vaccination.]

BLOOD SUGAR VERSUS URINARY SUGAR

To the Editor:—In *THE JOURNAL* June 17 and 24 appears a paper entitled "Blood Sugar versus Urinary Sugar" by Dr. Anthony Sindoni Jr. The author states that:

In view of the high incidence of disturbed carbohydrate metabolism frequently escaping detection by examination of the urine for sugar and the serious consequences resulting therefrom, blood sugar estimations, fasting and after meals, should be indispensable in early and latent recognition of the blood sugar disturbances:

- (a) They should be the governing factor in guiding the insulin dose and diabetic treatment.
- (b) Control of the hyperglycemia, not the glycosuria, should be the paramount aim of diabetic treatment.

The estimation of blood sugar levels is indispensable in the recognition of early and latent diabetes, but once the diagnosis has been made there is a question as to the relative value of blood sugar determinations. Diabetes mellitus is a metabolic disturbance not only of carbohydrates but also of proteins and fats, and in evaluating blood sugar levels one must be cognizant of the following points:

1. The glycogenetic and glycogenolytic mechanism of the liver. In diabetes mellitus the glycogenolytic mechanism in particular plays an exaggerated role.
2. That hypoglycemia affects glycogenolysis in the liver. This is an attempt to restore the blood sugar to its former level. Overstimulation of this glycogenolytic mechanism results frequently in hyperglycemia and glycosuria. "Hypoglycemia begets hyperglycemia" (Somogyi).
3. That glycogen is always removed from the liver during periods of hypoglycemia (Cori).
4. That glycogen can be stored in the liver only when the blood sugar level is augmented (Cori).
5. That ketone bodies are formed chiefly in the liver only when glycogen stores of the liver are depleted.

6. That there is a relative constancy of the respiratory quotient of well regulated diabetic patients although there is a wide fluctuation of blood sugars during the twenty-four hour period (Bridge and Winters).

Thus the mechanism that controls the rates of glycogenesis and glycogenolysis must be stabilized to avoid periods of hypoglycemia leading to glycogen depletion in the liver and ketosis. The latter is frequently followed by periods of hyperglycemia and glycosuria. Blood sugar levels within the so-called normal range may represent true hypoglycemic levels for diabetic patients. Hypoglycemic shock has been observed in diabetic patients with sugar content of the blood as high as from 120 to 180 mg. per hundred cubic centimeters of blood (Grafe). This same observation has been made by Mann and Magath in experimental depancreatized hepatectomized dogs.

While the harmful effects of hypoglycemia have been repeatedly demonstrated, those of hyperglycemia without ketosis are highly theoretical. In the management of diabetic patients it is advisable to adjust their diets and dosage of insulin so that a slight trace of glycosuria is maintained throughout the day, thus avoiding the possibility of hypoglycemia consistently. In this day of high carbohydrate diets it is felt that if the diabetic patient constantly utilizes a minimum of 90 per cent of the ingested carbohydrate he is in constant positive carbohydrate balance and is in no danger of ketosis. The respiratory quotients in these patients are high and approach the normal. It is felt that if any one factor is of prime importance in the welfare and management of the diabetic patient it is the state of liver glycogen, and no true indication of the state of liver glycogen can be obtained from blood sugar estimations in diabetes mellitus.

ZOLTON T. WIRTSCHAFTER, M.D., Cleveland.

"DENTAL CARIES AND DOMESTIC WATER SUPPLIES"

To the Editor:—I was much pleased with and interested in the editorial "Dental Caries and Domestic Water Supplies" (THE JOURNAL, September 16, p. 1132). I have had occasion to watch your part in this story of the relation of fluorine to dental conditions.

Only recently I have been shown "An Address on Tooth Culture" by Sir James Crichton-Browne in the *Lancet* of July 2, 1892. On page 7 is a paragraph discussing fluorine and dental caries in which he advises a supply of fluorine for child-bearing women so as to "fortify the teeth of the next generation." An enthusiastic follow-up on Sir James's suggestion at that time might have yielded some human experimental evidence of the causes of mottled enamel, so it is perhaps fortunate that such an application was not then made.

In your own columns may be found at least three items on fluorine and its relation to dental caries, one in the editorial columns Nov. 7, 1931, page 1389, and two in *Queries and Minor Notes*, Jan. 27, 1934, page 315, and June 9, 1934, page 1964.

An important paper which has received little attention is that of W. D. Armstrong and P. J. Brekhuis entitled "Possible Relationship Between the Fluorine Content of Enamel and Resistance to Dental Caries" (*J. Dent. Research* 17:393 [Oct.] 1938). Their analytic data are evidence from an entirely different angle of the relation of fluorine to dental caries.

My associates and I have experimental evidence contained in a paper to be published in the *Journal of Dental Research* that fluorine added to the diet of pregnant rats results in increased caries resistance in the young. This is an experimental approach which shows that fluorine is responsible for the increased resistance to caries, as it was the sole variable in our procedure. Our work on fluorine has been mentioned in the last three annual reports of the director of the Mellon Institute published in the "News Edition" of *Industrial and Engineering Chemistry*.

It seems therefore that, with three different lines of evidence of this beneficent dental effect of fluorine, namely the Galesburg-Quincy survey of Dean and his associates, the analytic data of Armstrong and Brekhuis and our experimental evidence, the case should be regarded as proved.

GERALD J. COX, PH.D., Pittsburgh.

Senior Fellow, Mellon Institute of Industrial Research, University of Pittsburgh.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PLEURAL PAIN AND PNEUMOTHORAX

To the Editor:—A man aged 32 has had artificial pneumothorax treatment of the right lung for the past six years. Previous to collapse therapy he had a pulmonary hemorrhage, the sputum was positive for tubercle bacilli and x-ray studies showed evidence of a moderately advanced lesion at the right lung with no apparent cavities. A short time after artificial pneumothorax was established, fever and cough subsided and the sputum became normal, as it has continued up to the present. Since a supplementary year of rest, the patient has been engaged in a suitable occupation. About six months after institution of pneumothorax, approximately a pint of pleural effusion developed, reaching to the fifth rib anteriorly. The fluid was not removed and remained in the pleural cavity for two years, when it suddenly absorbed, leaving x-ray evidence of "fibrin bodies" at the base of the thorax. The lesion in the lung is apparently healed, and at present and for several years there have been no indications of activity. However, there is this difficulty: If the patient does not have a refill every ten days, the pleural surfaces, which are apparently thickened, rub together and produce a mechanical pleuritis, which causes the temperature to rise as high as 100 or 101 F., with nausea and general malaise, the lung being in approximately 60 to 70 per cent collapse according to fluoroscopic and x-ray examinations. After a refill of from 400 to 500 cc. of air the fever subsides together with the pleural rubbing, and in a day or two all symptoms are gone. The patient is anxious to discontinue pneumothorax treatments because they are no longer needed to control the tuberculosis, but the complication mentioned prevents this. Can any procedures be instituted to alleviate this complication? Are there any studies in the literature on this phase of pneumothorax? What would you suggest as a possible way of discontinuing collapse without having these symptoms? Is it possible that fluid would develop and cause subsidence of symptoms, with eventual absorption permitting reexpansion of the lung? Would a nonirritating oil in small amount such as is used in oleothorax lubricate the pleural surfaces and thus prevent the pleural friction? Any suggestions or references will be greatly appreciated.

M.D., Pennsylvania.

ANSWER.—From the statements made it is assumed that friction rubs can be elicited over some part of the chest while the lung is still collapsed to 60 or 70 per cent of its volume. Thus it is assumed that the visceral and the parietal pleura are coming in contact at one or more points. After pleurisy with effusion, it seems probable that the pleura contains tuberculous lesions which cause no symptom as long as the lung is under a fairly complete state of collapse. The lesions may be anywhere over the surface of the pleura; that is, they are not necessarily limited to the area over the pulmonary disease. The mechanical effect of the two layers rubbing together in the region of pleural lesions may be sufficient to cause the symptoms. Again, the reexpansion of the lung to 60 or 70 per cent of its volume may result in enough stretching of the visceral pleura to reactivate lesions in it, even though it is not in contact with the chest wall. In fact, too rapid stretching of the pleura in reexpansion may cause its rupture. The pulmonary lesion may also be reactivated by expansion if it is not sufficiently fibrosed.

It is possible that reducing the amount of air of the ten day refills to 100 or 200 cc. might allow the lung to expand more gradually and thus prevent the symptoms, as this amount would be sufficient to reduce the negative intrapleural pressure. If this does not suffice, temporary interruption of the right phrenic nerve so as to paralyze and elevate the diaphragm, thus reducing the size of the pleural cavity, might be given a trial. Following temporary interruption, the nerve fibers regenerate in approximately three months. If this procedure aids in preventing the symptoms, it could be repeated one or more times if necessary, while the lung is being expanded.

The introduction of sterile olive oil or liquid petrolatum up to 100 or 200 cc. might suffice while the lung is reexpanding. Oil has a strong tendency to cause thickening of the pleura since

it is a mild irritant, and therefore it should not be left in the pleural cavity more than a few months at a time. In some cases it causes so much change in the visceral pleura that it becomes impossible for the lung ever to reexpand.

There is the possibility that fluid will form again if the symptoms are permitted to continue, that is, if no air is introduced. In some such cases empyema develops; therefore it would seem safer to employ the procedures outlined.

If from these various procedures no relief from symptoms is experienced as the lung reexpands, it is probably safer to keep the lung collapsed by pneumothorax to the point just below the appearance of symptoms over a longer period, so that in case there are still lesions in the pleura, which are easily activated, they will be given a better opportunity to come under control.

EAGLE FLOCCULATION TEST

To the Editor:—Will you please send me information about the Eagle flocculation test for syphilis: 1. What is its present standing as an authoritative laboratory test? 2. In what respects is it superior to the Kahn test on (a) untreated and on (b) treated patients? 3. In what physical conditions are false positive reactions likely to be found? 4. Do you advise its substitution for the Kahn test or its use as a check on the Kahn test in a laboratory which employs no pathologist?

M.D. Florida.

ANSWER.—1. The Eagle flocculation test has been designated by the American Serologic Committee as a reliable laboratory procedure for the detection of syphilis.

2. With regard to treated and untreated syphilis, it is impossible at the present time to discuss the superiority of either the Eagle flocculation or the Kahn precipitation test, principally because of the small number of cases on which an authoritative evaluation has been made from this standpoint. Studies thus far, however, seem to give the two tests an approximately equal rating.

3. From the evaluation studies conducted in cooperation with the United States Public Health Service in 1935, and in the experience of various serologists, it has become recognized that flocculation tests in general may give appreciable numbers of false positive results in leprosy, yaws and malaria. In occasional instances false positive results may be encountered in tuberculosis, relapsing fever, infectious mononucleosis, gonococci, pneumococci and streptococci infections, jaundice and malignant conditions and rarely even in a person without recognizable disease.

4. Since the evaluation studies of the United States Public Health Service reveal that both the Eagle and Kahn tests are efficient procedures for the detection of syphilis from the standpoint of sensitivity and specificity when performed in reliable laboratories by properly trained technicians, there should be no valid reason for substituting either test for the other. To use the one procedure as an intralaboratory check on the other, however, obviously would be of merit.

PARALYSIS AFTER RABIES VACCINE

To the Editor:—Please give me symptoms, prognosis and treatment of a condition called peripheral paralysis caused by the use of rabies vaccine. All I can find in Meakin's Practice of Medicine is "There is no proven explanation for such, and they are principally of an academic interest." It happens once in 5,000 inoculations. However, it is important from the patient's point of view.

E. M. Ling, M.D., Hemlock, Mich.

ANSWER.—The latest figures on the occurrence of postvaccinal paralysis from the *Bulletin of the Health Organization of the League of Nations* showed the frequency of paralysis in patients receiving Pasteur antirabic treatment to be thirteen among 121,000 treatments, or one in 10,729. For the entire eight reviews the proportion of accidents has been one in 5,441, or 139 out of 756,000 treatments. It is now readily apparent that killed phenol, heated, and killed ether methods of preparing the vaccine are alike satisfactory regarding the incidence of accident. Nearly all patients have been adults. Two thirds had the onset during treatment and one third soon after its termination. The time of onset has been from eleven to thirty days after the bite for which the treatment was given. This is a much shorter period of incubation than that for rabies. The incubation period of the latter is usually from forty to sixty days. Three clinical types may be distinguished:

Type 1, acute ascending paralysis of Landry. The onset is sudden, with fever, headache, vomiting, severe backache, insomnia and restlessness. The following day the legs are weak and in one or two more days the paralysis is apt to be complete. The sphincters are also paralyzed. Pain, which is usually present in the back, extends upward into the neck and chest, and then the arms become paralyzed. This is followed by pains

in the face and paralysis of the throat (bulbar) and face. The prognosis in this type is grave because of bulbar paralysis (respiratory and circulatory arrest). The mortality is about 30 to 40 per cent.

Type 2, dorsolumbar myelitis. The onset is gradual and the fever at first is slight. The legs become completely paralyzed and anesthetic. The sphincters are also involved. The tendon reflexes are lost but occasionally there is a Babinski sign. There are no bulbar signs. Recovery usually occurs in the course of several weeks unless bed sores and urinary tract infection result in lowering the resistance and causing death by sepsis.

Type 3, neuritic form. After a brief febrile period one or more peripheral nerves become involved and cause paralysis. The facial nerve is by far the most frequently concerned. The facial paralysis may be unilateral or bilateral. Other nerves that may become affected are the oculomotor, vagus, radial, ulnar and sciatic. Rapid recovery is usually the rule. The treatment is essentially that of any acute infection, with absolute rest, forcing of liquids and aseptic care to bed sores and urinary abnormalities. The neuritic forms may be treated with local massage and galvanic current after the period of acute involvement. This usually occurs after the second or third week when the temperature is normal. The patient should be placed on an air or water mattress. Foot and wrist drops should have proper immobilization. Vitamins B₁, B₂ and C should be given.

At the present time the various types of paralysis following administration of antirabies vaccine are supposed to be due to the vaccine itself and not to be original rabic infection.

FORDYCE'S DISEASE OF THE VULVA

To the Editor:—A young unmarried woman complained of itching of the labia minora. On examination I found a series of closely packed, pin-head size, light yellow papular lesions. The picture to a certain degree resembles Fordyce's disease of the mouth in that it consists of innumerable tiny faintly yellow lesions. There is a certain amount of itch, but it is not intolerable. There is no history in this case of syphilis, diabetes, *Trichomonas vaginalis*, gonorrhea, masturbation, contraceptives or the local application of irritating ointments. It is the first time that I have ever seen this condition and for all I know it may be common, but I would greatly appreciate your opinion as to the diagnosis.

William J. Macdonald, M.D., Boston.

ANSWER.—It is probable that this young woman does, indeed, have Fordyce's disease of the vulvar mucous membrane. Fordyce's disease may occur in this situation as well as in the mucous membrane of the lips and mouth. A noninflammatory dermatosis consisting of yellow, discrete puncta on the vulvar mucous membrane and in the mouth would not ordinarily fit in with any other entity. A peculiar type of localized xanthomatosis might be considered, but its presence is not likely. Of course, a biopsy would settle the question. Histologically, masses composed of cells resembling those found in sebaceous glands are found in Fordyce's disease.

Fordyce's disease is devoid of symptoms, the lesions generally being found accidentally. In consequence, the itching present must be accounted for on some other grounds. A moderate amount of pruritus of the vulva and anus is not rare, the causes of which are diverse. Some of these, such as *Trichomonas vaginalis*, the inquirer has not found present. It is assumed that no local cause for the itching can be found; otherwise that should be corrected.

Pruritus vulvae at the menopause and later may be due to changes in the secretions of the endocrine glands. A general examination should be made to rule out such possible causes as diabetes or nephritis.

If no disease process can be found to account for the itching, local measures may be used for symptomatic relief of the itching. Nothing need be done for the Fordyce's disease. Application of an antipruritic lotion, oil or ointment is indicated. The usual antipruritics are used, such as phenol, menthol and camphor-chloral. These may be employed in somewhat higher concentration than when their general application is required. Applications of moist dressings of water as hot as can be borne may at times tide one over an itching crisis. Painting with a 10 per cent aqueous solution of silver nitrate may be done once or twice a week. The most effective nonspecific agent for vulvar pruritus is the x-ray. Great care should be used not to go beyond a tolerance dose for fear of inducing a radiodermatitis. One fourth of a unit once a week for several weeks is sufficient in many cases. Some recommend local injection of such materials as alcohol and quinine and urca hydrochloride. These measures are seldom indicated and may prove dangerous. A certain experience with them is required. In exceptional cases surgical measures have been employed, but most observers are not in favor of them.

UREA AS DIURETIC

To the Editor:—I would appreciate any information that you may be able to give me as to the use of urea for elimination in cordiae decomposition.

H. S. Rosenberg, M.D., Franklin Square, L. I., N. Y.

ANSWER.—The use of urea as a diuretic in cardiac insufficiency as well as in renal disease was established about twenty years ago in German clinics. The first careful clinical study in the United States was reported in 1925 (Crawford, J. H., and McIntosh, J. F.: *Arch. Int. Med.* 36:530 [Oct.] 1925). Since then urea has achieved only moderate popularity as a diuretic and in recent years has been largely displaced by the organic mercurials and acid-forming salts. The reasons for this are the limited diuretic effect of urea and its unpleasant taste. The mechanism of its action was recently discussed in *Queries and Minor Notes* (Urea as Diuretic, *THE JOURNAL*, June 4, 1938, p. 1945).

It is necessary to give from 30 to 60 Gm. of urea daily to produce diuresis. The 40 or 50 per cent aqueous solution may be diluted with an equal volume of some fruit syrup or taken in carbonated water, beer, tomato juice, coffee or tea. The daily dose is best divided into three portions, given after meals. The salt and fluid intake should be limited in order to favor the removal of edema fluid by the osmotic action of the extra urea. Since urea can readily be ingested as a 20 per cent solution but concentrated by the kidney to only 4 per cent as a maximum, diuresis will occur provided renal function is unimpaired. That urea has no deleterious effect even when taken daily for months or years has been fully demonstrated (Miller, H. R., and Feldman, A.: *Arch. Int. Med.* 49:964 [June] 1932). It may be advantageous to combine the administration of urea with the use of other diuretics, such as the organic mercurials. Urea is especially helped in preventing the recurrence of cardiac edema after the original dropsy has been controlled by rest, digitalization and ordinary diuretic management. For this purpose a dose of from 15 to 30 Gm. a day may be sufficient. In general, the use of urea will be determined by the patient's gastrointestinal tolerance for the drug.

COCONUT MILK AND DIABETES

To the Editor:—Can you give me any information regarding the value of coconut milk in the treatment of diabetes mellitus or refer me to the literature on the subject?

M.D., New Jersey.

ANSWER.—The composition of coconuts and coconut milk is as follows:

	Carbohydrate, per Cent	Protein, per Cent	Fat, per Cent	Calories per 100 Gm.
Coconuts	27.9	5.7	50.6	590
Coconut milk	4.6	0.4	1.5	34

As may be seen, coconuts are rich in fat and high in calories despite a relatively low carbohydrate content. Coconut milk is low in carbohydrate and in calories. These facts may be responsible for a reputed value of these foods in diabetes. No other information on the subject has been found.

Reference:

Joslin, E. P.: *Treatment of Diabetes Mellitus*, Philadelphia, Lea & Febiger, 1937, p. 681.

LEAD CONTENT OF CRAYON CHALK

To the Editor:—Recently there have been articles commenting on lead poisoning resulting from the use of chalk containing lead chromate. In this connection some of the crayon companies state that their chalk is nontoxic. Have you any data proving whether or not chalk may have small amounts of lead and still be nontoxic? As I understand lead poisoning, lead is cumulative. Therefore a person exposed to lead, either by inhaling dust or by nibbling chalk containing lead even though in small amounts, would possibly be accumulating enough lead actually to cause poisoning. The points that I would like to have answered are: What amount of lead in chalk would be toxic, or would chalk have to be absolutely free of lead to be considered nontoxic?

Malvin J. Nydahl, M.D., Minneapolis.

ANSWER.—In 1937, C. M. Jephcott (Lead in Certain Coloured Chalks and the Danger to Children, *Canad. Pub. Health J.* 28:391 [Aug.] 1937) reported finding high concentrations of lead chromate in yellow, orange and green crayons but no lead in other colored chalks. Chalks recently analyzed by the Massachusetts State Division of Occupational Hygiene, under the direction of Manfred Bowditch, were found to contain between 2.2 and 18.7 per cent of lead. These high percentage chalks would seem to be definitely undesirable for children to use, particularly because of the dust which they produce. Crayon manufacturers are now cognizant of this risk, and it is believed that this high lead content already has been eliminated from some colored chalks. One cannot say exactly how much lead would be permissible in that chalk. The factor of importance is the amount of lead present in the air which is

breathed. A larger percentage of lead in chalk would be safe if blackboards were cleaned with water rather than with the dust-producing eraser. The usual safe limit of daily lead absorption is stated to be about 2 mg. a day in breathed air. Somewhat larger amounts could be taken by mouth without deleterious effects. Therefore chalk would not have to be absolutely free of lead to be considered nontoxic, but it ought not contain a large percentage of lead. Certainly the high percentage now found in some chalk should be reduced, no matter what chemical compound of lead is employed.

EFFECT OF SULFANILAMIDE ON GONOCOCCI

To the Editor:—It has repeatedly been stated that the use of sulfanilamide in the treatment of gonococcal infections may alter the morphology appearance of the gonococcus. A detailed report of the changed appearance of the sulfanilamidized gonococcus as observed microscopically would be appreciated.

Heinrich Lomm, M.D., La Feria, Texas.

ANSWER.—Under sulfanilamide therapy the slide characteristics of both gonococci and secondary organisms become unusually irregular. Size, shape, relationship to pus and epithelial cells and to a lesser extent staining characteristics change. The organisms may become unrecognizable and confused with one another. There are more extracellular organisms and the pus cells confusingly contain what may be a single organism or pair of organisms, a fragment of nuclear material or merely debris. The gram-negative short coliform bacilli in the early division stage can easily pass for gonococci. They may be intracellular.

The most reliable diagnostic criteria are cultural. Atypical gonococci always revert to type when implanted on suitable soil, whether it is a laboratory medium or the urogenital epithelium.

POSSIBLE SCIATIC OR PERINEAL HERNIA

To the Editor:—Please suggest possible diagnoses or diagnostic procedure in the following case: A white woman aged 36, 5 feet 6 inches (168 cm.) tall, weighing 235 pounds (106.6 Kg.), complains of a large "lump" present on the upper outer quadrant of the left buttock. This "lump" is transient, appearing within a space of a few hours, persisting for several hours or days and finally disappearing as rapidly as it came. It has been present intermittently for the past six months. The time of appearance does not seem to be influenced by activity. There is some pain associated with this mass—at times referred medially to the region of the sacroiliac joint and at other times anteriorly to the groin. There is moderate discomfort on walking because of its size. The past history reveals three normal pregnancies, no miscarriages and no previous infectious diseases. She has complained of some pain in the left thigh of an indefinite nature for years. About six months before this swelling made its appearance she had a large earbuncle on the left knee. This is entirely healed at present. Physical examination reveals nothing of interest other than marked generalized obesity. On the upper outer quadrant of the left buttock is a swelling the size of a large grapefruit. There is no discoloration or fluctuation. It is apparently a muscular swelling and is only slightly tender. The upper edge reaches the crest of the ilium posteriorly. The temperature, pulse, blood pressure, urine and blood count are normal and the Wassermann reaction is negative. X-ray examination of the hip joint and adjacent structures revealed no pathologic condition. The patient was seen a day later. She stated that the mass had disappeared during her sleep the night before. Examination then showed no deviation in the normal contour of the buttock. About two days later, however, the patient returned with the mass present again; it had appeared that morning while she was baking and looked essentially the same as before.

M.D., Pennsylvania.

ANSWER.—This is an unusual case and certainly warrants careful study. The transient nature of the swelling excludes neoplasms of the soft part. Moreover, x-ray examination excludes neoplasms originating from the bone. It would seem that this swelling must be either some type of hernia or a fluid collection which has an hour-glass shape permitting the fluid to go back and forth from one to the other of two compartments. Hernia seems the more likely explanation, although the situation high on the buttock is hard to explain.

About thirty cases of sciatic hernia have been reported. In this condition the hernia emerges from the pelvis through the sacrosciatic notch and protrudes into the folds between the buttock and the leg (Andrews Edmund, in *Textbook of Surgery* Frederick Christopher, editor, Philadelphia, W. B. Saunders Company, 1936). This type of hernia is best repaired by laparotomy, and great care should be exercised to avoid injury to the sacral plexus.

In perineal hernia the herniation is through the pelvic floor, but in the posterior type of this hernia it emerges behind the transverse perineal muscle. It is possible that one of these rare types of hernia may explain the condition. Help to substantiate the diagnosis of hernia might be obtained by the x-ray film showing gas bubbles in the soft part as of loops of small intestine. Or, if an x-ray film of the gastrointestinal tract could

be taken when the swelling is present it might show barium-filled loops outside the pelvis. Aspiration would seem to be somewhat risky.

A rupture of the insertion of the gluteus muscle with bunching up of this muscle toward the crest of the ilium might be considered, but this would be constantly present with every effort to contract the gluteus.

After all other efforts at diagnosis have been exercised, this case would warrant surgical exploration from the outside.

DIGITALIS AND EPHEDRINE

To the Editor:—In *The Journal*, May 16, 1931, Johnson and Gilbert advised that "when digitalis is being used for the heart, ephedrine should not be used or with extreme caution." Has this been substantiated by other observers? Luten in his book *The Clinical Use of Digitalis* (Springfield, Ill., Charles C. Thomas, 1936) mentions Johnson and Gilbert's statement, page 127.

H. B. Aitkens, M.D., Le Center, Minn.

ANSWER.—The work of Johnson and Gilbert has neither been confirmed nor denied. It would only rarely be of importance clinically. Clinical doses of digitalis seldom reach 50 per cent of the minimal lethal dose. The lethal dose of ephedrine in the anesthetized dog is 70 mg. per kilogram, but in the unanesthetized dog it is about 40 mg. per kilogram. It is improbable that any clinical dose of ephedrine could possibly approach half this figure. On the other hand, if enough digitalis had been given to increase the irritability of the cardiac muscle up to a certain point, a moderate dose of ephedrine might further increase irritability and result in ventricular fibrillation and death. Digitalis, of course, should never be given to such a point.

The experimental work indicated a definite synergistic action between the two drugs. While fatal results clinically would be unlikely, except with a dosage of either drug which would never be necessary and which should never be used, it is just as well to bear in mind that experimental work does show a definite synergism, and they should be used with a moderate degree of caution.

EFFECT OF HIGH INTRACRANIAL PRESSURE ON PULSE AND BLOOD PRESSURE

To the Editor:—What influence does a rise in intracranial pressure of from 400 to 800 mm. of water have on the pulse rate and blood pressure? The literature is contradictory. Do you know any references to reports of cases, traumatic or otherwise, characterized by (1) a high cerebrospinal fluid pressure (but not high enough to approach the level of the systolic blood pressure), a lowered pulse rate and a rising blood pressure and (2) a return of pulse rate and blood pressure to normal when the intracranial pressure has been sufficiently reduced?

M.D., New York.

ANSWER.—In the presence of increased intracranial pressure the pulse is usually, but not always, slow until the breaking point of compensation, when it becomes increasingly rapid. In many instances, however, the pulse rate is not affected. The blood pressure is usually not altered but at times is increased slightly when the rise in pressure is sudden or rapid. The bradycardia will return to normal within a week or two after relief of intracranial pressure. There seem to be no precise records on this point, but the facts as given are well recognized in all clinics where intracranial pressure is commonly seen in the presence of tumors or cranial trauma.

DERMATITIS FROM ROCK WOOL

To the Editor:—Do you have any information concerning a dermatitis occurring among insulators who handle rock wool? What type of dermatitis is most common and is there definite evidence that the rock wool is the etiologic factor? What have been the most successful means of preventing this dermatitis? In other words, if there have been any reports of such a dermatitis I would appreciate learning as much about it as possible.

Ralph E. Jones, M.D., Chicago.

ANSWER.—Rock wool, slag wool, slagbestos or mineral wool is made by blowing air and steam through iron blast-furnace molten slag or through natural siliceous limestone or calcareous shale rocks when in a molten state. This converts the slag or rock into fine threads like cotton wool which are insect and fire proof. The product is used as an insulating material, a filtering medium, a covering for steam pipes and for packing.

Occupational dermatitis attributed to rock wool and confirmed by positive patch tests has previously been reported to the Office of Dermatoses Investigations of the U. S. Public Health Service. The irritating properties of this substance are said by R. Prosser White (*The Dermatogoses or Occupational Affec-*

tions of the Skin, ed. 4, London, H. K. Lewis Company, Ltd., 1934) to be due to its content of quicklime, 10 per cent, and calcium sulfide, 5 per cent, as well as to spicules which it contains. Its dust is said to be irritating also to the mucous membranes of the nose and eyes.

Since its alkaline content and the spicules it contains are said to be the causes of dermatitis from this material, it would seem that the wearing of rubber gloves and dust-proof clothing, with frequent changes of work clothes and cleansing shower baths after work, would offer the best protection against this occupational hazard to the skin. The use of protective ointments, especially those which are said to give protection against alkalis, may also be of benefit.

MIGRATION OF TESTES

To the Editor:—A boy now 10 years of age was seen shortly after birth, at which time he had an undescended right testis with the left testis in the scrotum. A few months later there was torsion of the right testis with gangrene, requiring its removal. I saw the boy recently and the left testis was still in the scrotum and was about the size of a pea. The mother showed me his brother, aged 7 years, whom I also saw at birth, and I know that both testes were normal at that time and were in the scrotum. When I saw the boy yesterday neither testis could be palpated and there was no evidence of any hernia. The youngest son, aged 4 years, has a small left testis with no evidence of a right testis. I know likewise that at birth he had both testes in the scrotum. I should like advice as to the prognosis and treatment.

M.D., Massachusetts.

ANSWER.—With regard to the boy aged 10 years who had one testis removed for gangrene because of torsion, as long as the left testis is in the scrotum one should do nothing and merely keep the boy under observation. It would be desirable to have the boy see his physician once a year.

With regard to the boy aged 7 years, in whom the testes were normal and in the scrotum at birth, it is stated that the physician saw the boy recently and neither testis could be palpated. It is well known that in some patients the testes do retract and move up and down—a phenomenon that has been recognized for a long time. It is failure to recognize this which leads to erroneous diagnoses. Some of these patients are prepared for operation for undescended testes, and just before the operation is started the testes are found in the scrotum. In several observed instances in which the testes moved up and down they ultimately found their way into the scrotum and stayed there.

The same explanation will suffice for the boy aged 4 years. He should be kept under close observation. Some patients who belong to this group and in whom this condition is not recognized are given long courses of endocrine treatment and the descent of the testes is erroneously ascribed to the use of the endocrine substance.

To sum up, these boys should report to the physician's office once a year. Nothing should be done in a surgical way and certainly they should not be given endocrine therapy.

TABES WITH NEGATIVE SEROLOGIC REACTIONS OF THE BLOOD AND SPINAL FLUID

To the Editor:—Is it possible to have syphilis of the central nervous system with repeatedly negative Wassermann and Kahn reactions of the blood since childhood and a spinal fluid in which the cell count is 1 and the colloidal gold curve and the Wassermann reaction are negative and globulin normal? The patient has a fixed, dilated right pupil, the knee jerks are absent, the Romberg sign is absent, there are questionable saber shins, there is a backache with questionable root-pain type of radiation and she is married to a man who has tabes but who was treated moderately before marriage.

M.D., New Jersey.

ANSWER.—It is possible, in fact it is noted quite frequently in a syphilologist's practice, that patients with clinical signs of tabes dorsalis will have negative reactions of the blood and spinal fluid. These are known as "burnt out tabetics" and the negative serologic reactions may have developed in one or two ways, either as the result of treatment or spontaneously. The latter group are less numerous and, although these serologic negative reactions developed without treatment, the use of arsenphenamine and bismuth compounds does not control the persistent symptoms such, for example, as the neuritis of tabes. The evidence presented in the inquiry is not enough on which to base a conclusive diagnosis of tabes, since some neurologists believe that such suggestive clinical manifestations might be the residue of a nonsyphilitic inflammatory lesion of the central nervous system. The fact that the husband has tabes increases the possibility that the patient under discussion may have had syphilis. Even so there is little that can be done for her, since antisyphilitic therapy in such cases offers but slight relief.

Virginia June Examination

Dr. J. W. Preston, secretary, Virginia State Board of Medical Examiners, reports the written examination held at Richmond, June 21-23, 1939. The examination covered eight subjects and included eighty questions. An average of 75 per cent was required to pass. One hundred and three candidates were examined, 102 of whom passed and one failed. The following schools were represented:

Book Notices

Treatment in General Medicine. Edited by Hobart A. Reimann, M.D., Magee Professor of Practice of Medicine and Clinical Medicine, Jefferson Medical College, Philadelphia. In Three Volumes and Desk Index. Cloth. Price, \$30 per set. Pp. 895; 1001-1896; 2001-2334, with illustrations; 107. Philadelphia: F. A. Davis Company, 1939.

Recognizing that advancement of modern medicine has made medical problems so highly specialized that it is no longer possible for one individual to cover completely any single medical field, Dr. Reimann has developed a system of therapeutics in which distinguished specialists consider various phases of the treatment of individual diseases. Since treatment must depend on knowledge of cause and on symptoms, space is given to these subjects and also to considerations of other factors in disease intimately associated with treatment. It is recognized that psychotherapy is an intimate part of all the treatment of disease, and special attention is also given to this aspect of medical care. Finally, the volume includes discussions of minor surgical, gynecologic and obstetric treatment, as well as a chapter of the conditions associated with old age. The volumes are important also because they emphasize standardized and controlled treatment. Thus the remedies concerned are those available through the United States Pharmacopeia, the National Formulary and New and Nonofficial Remedies. In line with the recommendations of standard therapy, the work begins with a foreword by the editor of THE JOURNAL discussing the basis of scientific therapy. Thereafter the volume takes up, in the usual order, the treatment of infectious conditions, parasitic diseases, the heart the blood vessels, the gastrointestinal tract and the genitourinary tract. There are excellent discussions of prophylaxis. Selected bibliographies indicate to the reader the places for further detailed study. The list of contributors includes many of the best known names in modern medicine. In the final volume there are chapters on technical therapeutic procedures, irradiation, all of the various forms of physical and occupational therapy, and finally chapters on rest and the use of spas. This is a modern, direct, useful system of treatment.

The Surgical Treatment of Hypertension. By George Crile. Edited by Amy Rowland. Cloth. Price, \$4. Pp. 239, with 52 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

This work is a conglomeration of theories, facts, fallacies, scientific and pseudoscientific observations and unwarranted assumptions, welded together loosely in an unconvincing manner and in a style in which repetition and reiteration are apparently used to bolster the faltering argument. The constant assumption of unproved facts and the wide digressions into far flung fields of investigation, fields which are evidently unfamiliar to the author, confuse rather than clarify the subject. Many of the basic principles on which the flimsy superstructure is built are false or are erroneously interpreted. Controversial points are assumed to be definitely established. One is impressed with the apparent superficial knowledge of the author regarding much of present day physiologic concepts and especially of the functions and modus operandi of the sympathetic nervous system.

Considerable space is devoted to a comparison of the brains, thyroids, adrenals and celiac ganglions of fish, python, alligator, lion, tiger and man in the hope of promulgating a general law that the size of these organs determines the oxygen requirements and speed of oxygen utilization. "The size of the brain and the thyroid gland, the adrenal glands, the sympathetic system, the celiac ganglia, the aortic plexus, the heart, the volume of blood, the richness of the capillaries—all of these would be governed by a general law of energy release." It takes considerable imagination after reading the entire book to see just what this has to do with hypertension in man. However, except in small mammals and birds, Crile finds, "man is mechanized for the highest energy requirements of any animal on land or in the sea."

The next chapter indicates that it is a pathologic physiology of this mechanism governing the rate of oxidation and the circulation which produces hypertension. Later he suggests that only individuals who have abnormally large celiac ganglions and plexuses can have hypertension.

Medical Opinions on War. Published on behalf of the Netherlands Medical Association (Committee for War-Prophylaxis). Paper. Pp. 72. New York, Amsterdam & London: Elsevier Publishing Company, [n. d.]

In the old classical legend, Hercules, god of Force when engaged in a wrestling match with the young giant Antaeus, was surprised to find he could not overthrow him. Finally he learned the secret—that his young opponent was gegenes, earth born, and that, so long as he kept one of his feet on the earth, strength was imparted to him against which no external power could prevail. So the Olympian lifted Antaeus clear of his Mother Earth and, there and then, crushed him to death in his arms.

Investigations on the Sterilization Efficacy of Gaseous Formaldehyde.
By Gunnar Nordgren, Med. Lic. Acta pathologica et microbiologica
Scandinavica, Supplementum XL. Paper. Pp. 165, with 11 illustrations.
Copenhagen: Elnar Munksgaard, 1939.

Briefly, the reviewer understands that the sterilization efficacy of formaldehyde is greatest in an atmosphere of water vapor saturated with formaldehyde gas but that instruments should not be wet when placed in the sterilizer and the condensation of water during the process of sterilization should be avoided. In the author's experiments gas pressure, vapor pressure, time of exposure and temperature were carefully controlled. Heat was found to enhance the bactericidal action of formaldehyde. Recovery of organisms after exposure to formaldehyde was more frequent after the use of a sulfite solution; ammonia was of little or no value as a neutralizing agent. "The bactericidal efficacy depends upon the relative moisture of the gas, in all probability through the effect it has on the dried condition of the bacteria (spores) themselves. Dry formaldehyde gas is

nevertheless able to kill even spores which are in a very dry condition. . . . The gas has at least as strong sporicidal effect on spores which are not dried up as would have a formalin solution with which the gas is in equilibrium. . . . Sixteen experiments comprise simple sterilization tests carried out with seventy strains" of spore forming and non-spore forming bacteria and molds. For these tests the "test objects" were pieces of glass on which the organisms had been smeared and allowed to dry at 37 C. for from fifteen to twenty minutes. "In all cases the test objects were found to be sterile within a shorter space than an hour under the effect of air which, at room temperature (20-22 C.), was from half to three quarters saturated with formaldehyde and approximately saturated with water vapor." Greater difficulties are encountered in the sterilization of coarse particles of soil, porous materials and instruments with canals such as catheters. "For a safe sterilization of urethral catheters not even the 'formalin-vacuum principle' at 60° and an operation time of one hour is adequate. . . . Improvement is possible through previous evacuation followed by a relatively quick rise of pressure (by letting in air having a relative percentage of formaldehyde and water vapor as high as possible). . . . It must be pointed out that it is the rise of pressure as such, not the vacuum itself or the absence of air, which causes the penetration of the formaldehyde gas."

"The present prevailing opinion on formaldehyde sterilization must be completely changed. It should be unmistakably borne in mind that, although gaseous formaldehyde, as such, has a rather strong bactericidal efficacy, it has a very limited capacity to sterilize without the aid of specific technical expedients. Under such simple technical conditions as afforded by the Janet and Albarran principles, formaldehyde sterilizations can only be employed for very special purposes and with great precautionary measures. For more general purposes — for most of the objects which, in present day praxis, are treated in the Janet and Marion apparatuses — formaldehyde sterilization can only be made use of with the help of more complicated technical devices." The author describes the principles and uses of two such devices: (1) "a specific apparatus having no vacuum device, for the sterilization of one single instrument", such as an object "of simple shape, lacking canals or crevices, for instance, a simple endoscope"; (2) "an apparatus with a vacuum device for general purposes" in which alternate evacuation and admission of air saturated with formaldehyde may be employed.

A College Course in Hygiene. By K. Frances Scott, Ph.B., M.D., Associate Professor of Hygiene, Smith College, Northampton, Massachusetts. Boards. Price, \$2.50. Pp. 202, with 48 illustrations by Dr. William Dunlop Sargent and Margaret J. Sanders. New York: Macmillan Company, 1939.

This is an excellent college manual evidently intended for use primarily in Smith College for Women. The approach is biologic. The first chapter deals with the biologic nature of the body. Subsequent chapters in part I, which is devoted to hygiene as it concerns the individual, deal with the body's equipment for motion, equipment for energy production, the secretory function or chemical laboratory, the transportation systems (circulatory), metabolism and excretion, breathing, temperature control, equipment for acquiring information and equipment for coordination. The material is clearly, logically and briefly presented with numerous simple diagrams, charts, schematic drawings and silhouettes. The selection of material for practical usefulness has evidently been made with great care and excellent judgment. Elimination of extraneous material has contributed to the brevity of the work and yet is sufficiently complete to give the student an excellent orientation with relation to personal health. The second section is devoted to hygiene as it concerns the group, dealing with the human being's equipment for group living, his position as part of the race, and subsequent chapters taking up physical environment, control of the sources of supply, communicable diseases, special health needs and group agencies (public and private) for protecting health. Particularly complete, restrained and sensible are the sections relating to vitamins, stimulants, depressants, mental hygiene, sex and the venereal diseases. The venereal diseases are dealt with in connection with communicable diseases as is appropriate, and the sexual function is discussed in the chapters on the human being as part of the race immediately following the chapter on the human being's equipment for group living. The workbook

section is commendably brief, consisting of knowledge tests and personal inventory on general health, nutrition, food habits, colds, sleep, periodic function and civic health knowledge, plus ventilation surveys and lighting surveys. There is a brief but adequate index. Brief reading suggestions follow each chapter. The most frequent reference given in these reading lists is to *Hygeia*, the Health Magazine. The book can be recommended without reservation for use in institutions where women are taught or as a study manual for adult groups of women anywhere.

Grundriss der Geschlechtskrankheiten. Von K. Zieler. Third edition by Dr. Georg Birnbaum, o. Professor und Direktor der Universitätsklinik und Poliklinik für Haut- und Geschlechtskrankheiten in Königsberg/Pr. Boards. Price, 4.90 marks. Pp. 213, with 19 illustrations. Leipzig: Georg Thieme, 1938.

This is the first revision of "Zieler's Grundriss" in more than fifteen years. It is a brief discussion of the field of venereal diseases including gonorrhea, syphilis, soft chancre, venereal warts and nongonorrheal infections. This edition is by Birnbaum, a pupil of Zieler's. During the intervening years since the second edition political changes in Germany have definitely established the combating of venereal diseases as a public health problem. Therefore a brief discussion of the legal aspects of these diseases has been included. In the introduction, the point that prevention is more important than treatment is stressed. It is stated that there is little excuse for the continuance of venereal disease, it is so readily recognizable and treated. A third of the book is devoted to gonorrhea, including a brief discussion of the anatomy of the urethra, bacteriology, identification of the organism by staining and culture, the complications arising with treatment of each, explicit directions for examining both the male and the female, criteria for cure and a short discussion of the disease in children. Recent chemotherapeutic advances are not discussed, probably because the preparation of the book antedated them. Endocrine therapy in juvenile gonorrheal vaginitis is not discussed, nor is heat treatment. Complement fixation is regarded as merely a diagnostic adjunct. Vaccines are discussed at length. Soft chancre and venereal lymphogranuloma receive just a few pages; treatment of the latter with antimony and gold is briefly discussed. By far the greater part of the book is given to syphilis, including technique of preparation of the lesion for dark field examination, which the author believes is the most certain diagnostic point in recognizing syphilis. The lesions are thoroughly described and each drug is well discussed. Intramuscular mercury is favored by the author and the toxic effects are exhaustively shown. Malarial therapy is briefly discussed but no other forms of fever therapy are considered. In most respects the book fulfils the aim of the author. Many new trends in the field of venereal diseases are not included, probably because of the time element and the fact that the author intends to present briefly only facts that are certain.

Alcohol: Its Action on the Human Organism. By a Committee Originally Appointed by the Central Control Board (Liquor Traffic) and Later Reconstituted by the Medical Research Council. Third edition. Boards. Price, 30 cents; 1s. Pp. 176, with one illustration. New York: British Library of Information; London: His Majesty's Stationery Office, 1938.

In 1916 a distinguished British committee including such names as those of Cushny, Dale, Mott and Sherrington, later supplemented by Mellanby and Myers, prepared a statement on the effects of alcohol on the human body. In 1920 there was a careful revision, and a second edition appeared in 1924. The present edition has been prepared by a new committee, since some of the former members have died, and the book is now published on the authority of the Medical Research Council of Great Britain. It is an authoritative work as to the effects of alcohol on digestion and respiration and also considers its poisonous effects, its uses as a medicine, and the effect of alcohol on longevity. Here, it is the conclusion that mortality rates of persons especially exposed to the temptations of alcohol freely are unfavorable, but the statistical data now available do not suggest that a strictly moderate use of alcohol unfavorably affects the mortality rates of the users. The final conclusions are: "The temperate consumption of alcoholic liquors in accordance with these rules of practice may be considered to be physiologically harmless in the case of the large majority of normal adults; this conclusion, it may be added, is fully borne out by

the massive experience of mankind in wine-drinking and beer-drinking countries. On the other hand, it is certainly true that alcoholic beverages are in no way necessary for healthy life; that they are harmful or dangerous if the above mentioned precautions are not observed; further, that they may be definitely injurious for children and for most persons of unstable nervous system, notably for those who have had severe injuries of the head or who have suffered from attacks of mental disorder or from nervous shock."

Practical Dermatology and Syphilis. By Harry M. Robinson, M.D., Professor of Dermatology and Director of the Syphilis Clinic, University of Maryland School of Medicine, Baltimore. Cloth. Price, \$4.50. Pp. 397, with 439 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

Robinson presents a small textbook on dermatology which he states is "intended as an aid to the beginner in the study of dermatology (1) by helping him acquire a knowledge of the fundamentals of skin diseases, and (2) by showing how one may learn to recognize and diagnose the commoner diseases of this field." In his introduction he gives in a succinct manner a review of the "high spots" in dermatology with pertinent excerpts from some of the classic articles of the last decade. Since the work is intended as a small textbook on dermatology, the accounts are brief and there is no bibliography. There are forty-four pages on syphilis, and the subject on the whole is excellently treated. The illustrations are reproduced with a fair degree of accuracy. Figure 298, labeled Pemphigus foliaceus, shows a lesion in the left temporal area which impresses one as being more likely a patch of secondary vegetative dermatitis or epithelioma. The author deserves credit for knitting the details of his own diagnostic, clinical and therapeutic experiences into the text. While the book is an admirable small one and occupies a favorable position between the usual compend and the standard textbook on dermatology, it does not impress one as comparing with our better standard American textbooks.

Priests of Lucina: The Story of Obstetrics. By Palmer Flindley, M.D., F.A.C.S. Cloth. Price, \$5. Pp. 421, with 38 illustrations. Boston: Little, Brown & Company, 1939.

This book will be a welcome addition to the library of those members of the profession who are interested in medical history, whether or not they are obstetricians. It portrays the personalities of obstetricians, from the beginning of recorded literature to the present era, in a particularly interesting biographic style. The contents of the text are divided into two parts. Part one, comprising twenty-one chapters, presents in an especially readable way facts of obstetric history and biography. Part two deals with the history of special phases of obstetrics. Seldom does a book of this character present such a complete bibliography or one so well arranged for reference. To one interested in the history of medicine this is a treasure house of data. This alone should cause one to add the volume to one's library. The author states in the preface that he "has endeavored to select only the creative masters of the art, those who have contributed most largely to the making of an obstetric science, but it has not been possible to include all who have collaborated in the great work—it would be an endless task." He has selected well and made a decidedly valuable and interesting book.

Personality Changes After Operations on the Frontal Lobes: A Clinical Study of 32 Cases. By Gösta Rylander. Acta Psychiatrica et Neurologica, Supplementum XX. Paper. Price, 15s. Pp. 327, with illustrations. Copenhagen: Einar Munksgaard; London: Oxford University Press, 1939.

Any contribution on the functions of the frontal lobes of man is assured a large body of hopeful but apprehensive readers, for they have been disappointed often. Within this volume Gösta Rylander has gathered from the literature the salient opinions of other writers and has added a superb contribution of his own. The historical survey of twenty-seven pages covers the early epoch and the lessons learned from the study of brain injuries, tumors, Pick's disease, animal experimentation and partial excisions of the frontal lobes of man. The author's own contribution consists of follow-up examinations of thirty-two patients whose frontal lobes had been operated on from 1931 to 1938 in the Neurosurgical Clinic of the Serafimer Hospital. A critical selection of suitable cases, based on a study of the

excellent hospital records, was made. The author not only examined the patients by appropriate psychologic tests, of which he gives an informative description, but also visited them in their homes. He laid particular emphasis on appraising their adaptation to their work and to society in general. The case reports, which cover 169 pages, are followed by a survey of the results of the investigation, a discussion and summary, an appendix of tables and a helpful bibliography of fifteen pages. The felicitous selection of Mrs. Helen Frey as translator has given to the members of the profession an English rendition of a decidedly meritorious work on the personality changes after operation on the frontal lobes of man.

The British Encyclopaedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D. Volume XI: Scarlet Fever to Testis, Undescended. Cloth. Price, \$12. Pp. 676, with 94 illustrations. Toronto & London: Butterworth & Co., Ltd., 1939.

This volume is well up to the standard of the previous books in this system. The subjects discussed go from scarlet fever through such other main topics as sciatica, scurvy, sex hormones, sexual behavior and abnormalities, skin diseases, spinal cord diseases, spleen diseases, statistics, sterility, syphilis, and the testis. The authors are all British physicians of considerable note as investigators and practitioners in the fields of which they write. The volume is handsomely printed, profusely illustrated and well indexed.

A Textbook of Bacteriology: The Application of Bacteriology and Immunology to the Etiology, Diagnosis, Specific Therapy and Prevention of Infectious Diseases for Students and Practitioners of Medicine and Public Health. By Hans Zinsser, M.D., Consulting Bacteriologist to the Peter Bent Brigham Hospital and the Children's Hospital, Boston, and Stanhope Bayne-Jones, M.D., Professor of Bacteriology, and Denn, Yale University Medical School, New Haven, Connecticut. Eighth edition. Cloth. Price, \$8. Pp. 990, with 116 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1939.

Although there have been rapid advances in bacteriology and immunology in the last few years which have necessitated the addition of a good deal of material, this edition is somewhat smaller than the preceding one. The section on pathogenic protozoa has been omitted, and redundant and obsolete material in other sections has been deleted. Together with minor changes, this has provided space for the addition of material based on recent systematic studies of genera and species, bacterial variability, bacterial metabolism, chemical progress in refining of antigens, viruses and bacterial chemotherapy. Parts of the book make heavy reading and in some respects it is more suitable as a reference book than as a textbook for beginning students of bacteriology. The book will be used doubtless for both purposes quite successfully.

Travaux pratiques et démonstrations de pharmacodynamie. Par L. Dautrebande, professeur de pharmacodynamie et de pharmacologie, Faculté de médecine, Université de Liège, E. Philippiot, chef des travaux, F. Nogarède et R. Charlier. Paper. Price, 35 francs. Pp. 134, with 56 illustrations. Paris: Masson & Cie, 1938.

This laboratory manual on pharmacology is well organized and abundantly illustrated with kymographic tracings. In addition to the conventional pharmacologic experiments there is included material on such subjects as the carotid sinus and the technic of inducing gas anesthesia. The book goes briefly into the simpler chemical and biologic tests for poisons, and ten pages is devoted to methods for identifying war gases. On the whole, however, the book contains little that cannot be found in similar manuals published in this country. There is no index.

The Common Diseases of the Skin: A Handbook for Students and Medical Practitioners. By R. Cranston Low, M.D., F.R.C.P.E., F.R.S.E., Consulting Physician to the Skin Department, Royal Infirmary, Edinburgh. Third edition. Cloth. Price, 10s. 6d. Pp. 319, with 148 illustrations. Edinburgh & London: Oliver & Boyd, 1939.

This concise summary of present day dermatology gives the student and the practitioner an excellent introduction to the subject. The author's style is simple and easy to read, with emphasis on diagnosis and therapy of the commoner cutaneous disorders. In the chapters on eczema and urticaria the rôle of sensitization and focal infection is stressed. In the therapeutic sections most recent advances have been incorporated, although mention is not made of sulfanilamide and its possible uses in

dermatologic therapy or of the cutaneous reactions produced by it. In the chapter on drug eruptions mention should also have been made of phenolphthalein, phenobarbital and related compounds. The illustrations are well selected, including colored reproductions of moulages, black and white photographs, diagrams and characteristic histologic sections. Treatment in general is modern and not unnecessarily complicated. As an introduction to more complete volumes on dermatology, this book deserves unqualified approval.

A Classified List of Diagnoses for Hospital Morbidity Reporting. A Preliminary Report Based on a Study of 576,623 Hospital Discharges from 113 Hospitals in New York City in 1933. (WPA Project Number 665-97-3-54.) Welfare Council Publications 1939-IX. Paper. Price, 50 cents. Pp. 27. New York: Research Bureau, Welfare Council of New York City, 1939.

This is the first publication by the Welfare Council of New York City based on the results of the study of hospital discharges in New York City in 1933. The classified list of diagnoses of hospital morbidity reporting represents a study of nearly 600,000 discharges of patients from 113 hospitals in New York City. The diagnoses are based on the Standard Classified Nomenclature of Disease but for simplicity the diseases are listed under only 629 titles under such large divisions as "infectious diseases," "neoplasms," "neurology and psychiatric conditions" and "cardiovascular diseases." It will be most useful to some of the larger institutions and to those cities which desire to combine their morbidity figures from all different hospitals for extensive morbidity reports.

The Morphology of the Brachial Plexus with a Note on the Pectoral Muscle and Its Tendon Twist. By Wilfred Harris, M.D., F.R.C.P., Consulting Physician, St. Mary's Hospital, London. Cloth. Price, \$8. Pp. 117, with 87 illustrations. New York & London: Oxford University Press, 1939.

This excellent monograph describes the investigation of the different forms of the brachial plexus found in 158 varieties of animals from the amphibia to man. It followed the author's desire in 1902 to trace the different components of the fifth cervical nerve in a monkey with a view to a possible nerve anastomosis operation on a young child with a localized poliomyelitic paralysis of the deltoid and spinatus muscles. There are included sections of amphibia, reptilia, aves and mammalia, the latter including thirty human plexuses. The illustrations show various brachial plexuses and attachments of shoulder muscles (especially the pectoralis major). Harris explains the cutaneous supply of the median and ulnar nerves on the back of the hand and the motor supply of the ulnar nerve to the dorsal interossei in man by finding the dorsal fibers joining the ventral branches of the inner cord and distributed with the median and ulnar nerves. This monograph is highly recommended to all neurosurgeons and neuro-anatomists.

Health Problems in Negro Colleges. Proceedings of the First Regional Conference for Health Workers in Negro Colleges, Atlanta, Georgia, April 7 and 8, 1939. Paper. Pp. 63. New York: National Tuberculosis Association, 1939.

This pamphlet represents the proceedings of the first Regional Conference for Health Workers in Negro Colleges. This conference was called in Atlanta, Ga., by the National Tuberculosis Association, the American Social Hygiene Association and the Atlanta School of Social Work. It deals with general administrative problems related to the health of Negro college students under four principal headings: the tuberculosis problem, venereal diseases, health examinations and the improvement of hygienic teaching in Negro colleges. It should be of interest to all persons concerned with the higher education and social welfare of the Negro.

The Evolution and Organization of the University Clinic. By Simon Flexner, M.D. Paper. Price, \$1.25. Pp. 41. New York & London: Oxford University Press, 1939.

This little pamphlet combines two lectures given by Dr. Flexner at the Nuffield Institute in Oxford, England, in January 1938. The author traces briefly the development of the modern clinic and especially of the scientific laboratory, emphasizing the important features of organization of such modern institutions as the Rockefeller Institute.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Suspected Pregnancy or Ovarian Cyst; Failure to Use Friedman Test Negligence.—One of the plaintiffs, a married woman, consulted the physician defendant in either September or November 1934 relative to a possible pregnancy. The physician made a digital examination of the uterus. According to her testimony, he told her that she was pregnant. He testified, however, that he told her that she had an ovarian cyst, but she denied that he did so. Apparently she visited the physician's office from time to time thereafter and was examined, the physician defendant, according to the record, telling her repeatedly that she was pregnant. When she visited the physician in April 1935 her abdomen was distended and she complained that she had suffered severe pains during the previous month and had become very nervous. At that visit her husband asked her physician if there was not some way of determining whether his wife was or was not pregnant and her physician then suggested "the rabbit test," meaning thereby, presumably, the Friedman test or some similar test. The test was made and showed that the plaintiff was not pregnant. Thereafter an ovarian cyst about 6 inches (15.2 cm.) in diameter and weighing about 2 pounds (907 Gm.) was removed. The patient and her husband then sued the physician for malpractice. From a judgment in favor of the physician, the patient and her husband appealed to the Supreme Court of Washington.

In the course of the trial the plaintiffs offered to prove the number of "rabbit tests" that a chemist, the proprietor of a large local pathological and chemical laboratory, had made since 1931, the total number he made in 1934 and the number that he made for the defendant during that year. The trial court rejected the proffered evidence. The propriety of this rejection presented, according to the Supreme Court, the question to be determined on appeal.

It is well settled, said the court, that a physician must exercise that degree of care and skill which is ordinarily exercised by the members of his profession in the community in which he practices and in similar communities, having due regard for the state of medical and surgical science at the time. Ordinarily, whether a physician has exercised the degree of care and skill that the law requires is established by professional opinion, but this is not an invariable rule. There are instances in which facts alone prove negligence and it is unnecessary to have the opinion of persons skilled in a particular science to prove unskilled and negligent treatment. There is a difference, too, in malpractice cases, between mere errors of judgment and negligence in collecting beforehand data that are essential to the forming of a judgment. If a physician fails to inform himself as to facts and circumstances essential to the forming of a judgment and injury to the patient results from such failure, the physician is liable. Bearing these principles in mind, continued the court, we come to the question whether the chemist whose testimony was proffered should have been permitted to testify concerning the number of "rabbit tests" he had made.

The evidence showed that the "rabbit test" yielded correct results in 96 per cent of all cases. It was employed by physicians generally in the locality in which the defendant was practicing, in obscure cases. The physician defendant testified that the test was not in general use but was an aid and that he had from time to time employed it. Professional opinion was a unit in stating that where there was an ovarian cyst and the patient was not pregnant, it was correct practice to remove it, but that if the patient was pregnant it was correct practice to delay the operation, if it could be safely delayed, until after the birth of the child. An operation for the removal of the cyst while a patient was pregnant would in all probability result in the death of the child. In this case, the physician defendant testified that he suspected pregnancy and that he suspected also the presence of the cyst when he made the first examination of the plaintiff and that it was a matter of first importance when an ovarian

cyst was discovered to find out whether the patient was pregnant. The question then, continued the court, was whether the physician, in failing to employ the "rabbit test" earlier than he did and relying on the digital examination, neglected to collect data essential to a proper conclusion in the case. If he had discovered sooner that the patient was not pregnant, the cyst could have been removed earlier and the patient would have been saved from a long period of inconvenience and severe pain, resulting in a nervous condition.

The extent to which the "rabbit test" was applied in the locality in which the physician defendant practiced had a material bearing on the question of whether he was or was not negligent in not applying the test earlier. Courts have repeatedly held that the failure on the part of a physician to make a roentgenogram or to have a roentgenogram made as an aid to correct diagnosis, when x-ray machines are available and are commonly used by physicians in similar cases, may constitute actionable negligence. Applying the same principle to the utilization of the "rabbit test," it follows that the extent to which that test was utilized by physicians in the locality in which the physician defendant practiced was a material subject of inquiry in determining whether the physician was or was not guilty of negligence in failing to make use of the test at an earlier date. The testimony of the chemist which was proffered and rejected, said the court, was material and competent and its rejection was prejudicial error.

Judgment in favor of the physician defendant was reversed and a new trial ordered.—*Peterson v. Hunt (Wash.)*, 84 P. (2d) 999.

Workmen's Compensation Acts: Back Injury; Objective Evidence of Injury—Determinative Effect of Lay Testimony.—The claimant, in the course of his employment, attempted to lift a bucket of nuts and bolts weighing about 60 pounds. He felt a sharp pain in the lower part of his back and in his hips and could not lift the bucket nor straighten up. An osteopath, whom the claimant's foreman advised him to consult, found, so he testified later, "a severe injury to the ligaments and muscles in the area of the back, in the location of the first lumbar vertebra." He believed that "a fracture or injury of the vertebra had occurred." A company physician ordered the disabled workman to a sanatorium, where he remained nine days. After he returned home he remained in bed for about three weeks more. Thereafter he instituted proceedings under the Louisiana workmen's compensation act for compensation for total and permanent disability. The trial court rejected his claim and he appealed to the court of appeal of Louisiana, second circuit.

The employer contended that there was no evidence of objective symptoms of the alleged injury and that the Louisiana workmen's compensation act made such symptoms a condition precedent to an award of compensation. The court believed, however, that the evidence adduced met the requirements of the statute. The court pointed out that there was evidence that the claimant complained of his injury immediately after the accident; that his foreman and his fellow employees saw that he was injured and assisted him to the osteopath's office; that the osteopath recognized the injury; that the employer's physician sent him to a sanatorium, and that certain patients in that sanatorium observed the claimant's distress and suffering during his stay there.

To substantiate the defendant's contention that at the time of the trial the claimant was not suffering from any disability, it relied principally on the testimony of six physicians. Some of them had made clinical examinations of the claimant and others testified solely on the basis of roentgenograms. Their testimony was in irreconcilable conflict with the testimony of four physicians called on behalf of the claimant. In any case, said the court, in which the medical testimony is as conflicting as here, the court is forced to look to the lay testimony for a solution.

It is immaterial, continued the court of appeal, whether or not a claimant can prove the exact injury he suffered. It is sufficient in this case for the claimant to show that his back was injured and the location of the injury and the fact that the injury renders him unable to perform ordinary manual labor.

Were a workman required to prove the exact part of his back that was injured "he would be left to the mercy of the medical profession, which never fails to disagree as to the injury of a back." The lay testimony, however, in this case was overwhelmingly in the claimant's favor. It was shown beyond question that he had performed no manual labor since the accident and that on stated occasions he suffered pain and discomfort when he attempted to exert himself. The claimant, said the court, is either totally disabled to perform manual labor or he is an "A No. 1 malingeringer." The record does not justify this court in finding him to be a malingeringer. The court is, therefore, forced to find that he was totally disabled to perform work of a reasonable character at the time of the trial.

There is evidence in the record, said the court, that the claimant's back shows an arthritic condition. Practically all the medical witnesses testified that an injury to the back when in that condition will often cause a dormant arthritis to flare up and give trouble. Even if that is what happened, however, the injury is compensable.

The court accordingly entered a judgment in favor of the claimant.—*Phillips v. Yasoo & M. V. R. Co. (La.)*, 183 So. 43.

Hospitals: Nonprofit Hospital Corporation Not Liable for Negligence.—The plaintiff was born in a hospital Oct. 6, 1926. He was placed in a crib in the nursery with several other infants, among them a premature baby. To afford warmth for the premature baby an incubator was improvised, using as a source of heat an electric light globe. Either because of the defective condition of the electric wiring by which the globe was put into service or because of the close proximity of the globe to the cotton bedding, the crib in which the premature baby was lying caught fire. That baby was burned to death and the fire passed from the crib in which it was lying to the crib in which the plaintiff was sleeping, and the plaintiff was injured. On behalf of the injured child, his mother sued the hospital for damages. The jury returned a verdict in favor of the plaintiff, but on motion of the defendant a judgment was rendered in its favor notwithstanding the verdict. From that judgment, the plaintiff appealed to the appellate court of Illinois, first district, third division.

There is no controversy, said the court, as to the happening or as to the cause or result of the injury sustained by the plaintiff. It was conceded, too, that if the defendant in the case was a charitable organization as defined by the laws of the state of Illinois it was not liable for the negligence of its servants and employees. The provisions of the charter, said the court, determine the character of the organization and the purposes for which it was organized. Where a corporation, as shown by the terms of its charter, is operated not for profit and has no provision for the issuance of stock or the payment of dividends to incorporators or stockholders and where it appears that its purpose is to conduct a hospital, the law recognizes it as a charitable institution. The evidence, the court thought, was sufficient to prove the charitable character of the hospital defendant in this case. The injuries were grievous and would enlist sympathy if that were one of the elements to be considered in arriving at a decision, but under the law the court was obliged to hold that no liability attached to the defendant hospital.

The judgment of the trial court was affirmed.—*Marelick v. South Chicago Community Hospital (Ill.)*, 17 N. E. (2d) 1012.

Autopsies: Liability for Performance of Autopsy on Illegal Order of Justice of the Peace.—A workman, Love, instituted proceedings under the Texas workmen's compensation act for compensation for an injury allegedly due to his employment. Love died and a claim adjuster for the insurer of Love's employer procured from a justice of the peace an order for an autopsy. The autopsy was performed by the county health officer and another physician, each of whom was paid \$50 by the insurance company. Information obtained through the autopsy was used by the insurance company to defeat the claim for compensation. Love's brothers and sisters sued the insurance company for having unlawfully procured the performance of the autopsy without their consent. The trial court directed a verdict in favor of the insurance company, but the court of civil appeals of Texas, Beaumont, reversed that judgment and remanded the case for a trial on its merits. *Love v. Aetna*

Casualty and Surety Company (Texas), 99 S. W. (2d) 646; abstr. J. A. M. A. 109:387 (July 31) 1937. The insurance company then appealed to the Supreme Court of Texas.

In Texas, the Supreme Court pointed out, the authority of a justice of the peace to order an autopsy is derived exclusively from statute and may be lawfully exercised only for the detection of crime. It is to be presumed that a justice of the peace who orders an autopsy acts in the exercise of sound discretion and in good faith for the purpose of detecting crime, but this presumption is rebuttable. In the judgment of the Supreme Court, the testimony of the claim adjuster justified a finding that he had submitted the facts of Love's injury and death to the justice of the peace to induce that officer to order an autopsy for the purpose of determining whether or not Love had sustained a compensable injury and that the justice of the peace ordered the autopsy for that purpose. Such a finding by the jury would have destroyed the presumption of regularity of the justice of the peace's order for the autopsy and would have established that the justice of the peace ordered the autopsy for a purpose not authorized by law.

The Supreme Court of Texas therefore affirmed the judgment of the court of civil appeals, remanding the cause for a trial on its merits.—*Aetna Casualty & Surety Co. et al. v. Love et al.* (Texas), 121 S. W. (2d) 986.

Medical Practice Act (Utah): Revocation of License for Violating Narcotic Drug Act; Both Convicting Court and Licensing Agency Authorized to Revoke.—The medical practice act of Utah authorizes the Department of Registration to revoke or suspend the license of a physician guilty of unprofessional conduct, which the act defines to include, among other things, the prescribing of narcotic drugs in violation of law. The narcotic drug act of Utah, enacted subsequent to the enactment of the medical practice act, authorizes the court before which a physician has been convicted of violating its provisions not only to fine or imprison him but also, in its discretion, to revoke or suspend his license to practice.¹ Light, a licensed physician, was convicted of prescribing narcotic drugs in violation of the act, but the court did not revoke or suspend his license. The Department of Registration later instituted proceedings to effect that end. Light then petitioned the district court of Salt Lake County for a writ of prohibition to prevent further proceedings by the department. On demurrer, the trial court refused to issue such a writ and Light appealed to the Supreme Court of Utah.

The petitioner contended that the department had no jurisdiction to revoke or suspend the license of a physician convicted of violating the state narcotic drug act, since authority to revoke or suspend a license for such an offense was vested by the narcotic drug act itself exclusively in the court before which the physician was convicted. It is apparent, however, answered the court, that the state narcotic drug act intended to give the convicting court a power additional to that of fining and imprisoning a physician convicted of violating the act when it authorized it also to revoke or suspend his license to practice. If the court does not revoke or suspend the license, the Department of Registration, said the Supreme Court, still has the power to do so. This is shown by the fact that the clerk of the court, on conviction, is required by the act to send a copy of the judgment and sentence, together with the opinion of the court, if any, to the Department of Registration. If this sentence shows that the court has revoked or suspended a license, the department needs to go no further in that regard but has only the duty of seeing that the physician does not practice while his license is not in force. If the sentence does not include revocation or suspension, however, the department can proceed administratively to revoke or suspend the license of the convicted physician. Even independently of any criminal charge, too, the department may institute revocation proceedings. There is nothing inconsistent or incompatible in giving the court the power to revoke or suspend a

license and at the same time leaving in the administrative board or department authority to proceed to the same end.

Accordingly, the Supreme Court affirmed the judgment of the court below, in effect permitting the Department of Registration to institute and maintain proceedings for the revocation or suspension of the license of the petitioner notwithstanding the fact that the court did not do so.—*Light v. Golding, Director of Department of Registration* (Utah), 85 P. (2d) 114.

Cosmetology: Electrolysis as "Beautifying the Human Face."—In New York City no person may conduct a beauty parlor without a permit from the board of health. The Sanitary Code defines a "beauty parlor" as a place "wherein the business of . . . beautifying the human . . . face, . . . or hands, is conducted for fee, charge, or hire." The defendant practiced electrolysis in a one story house located in a residential zone. She had applied for a permit to operate a beauty parlor but her application was denied because the building department would not certify to the propriety of a business use in a residence zone or district. She was convicted of operating a beauty parlor without a permit and appealed to the supreme court of New York, appellate division, second department.

The defendant did no manicuring or massaging but confined her activities to the removal of hairs, by electrolysis, from all parts of the bodies of patrons. There is no doubt, the court said, that the removal of unwanted hair from the human face is commonly deemed "beautifying the human . . . face," within the meaning of the Sanitary Code. The fact that the defendant removed hair from the body, not mentioned in the Sanitary Code, as well as from the face and hands, did not exclude her activity from the purview of the code. To interpret the provisions of the code so as to enable a person who does certain types of work, not mentioned therein, also, without a permit, to do work specifically within its terms, when the latter work is general and not casual or sporadic, would, the court said, be to nullify the statutory provisions and countenance clear evasion thereof. The removal of hair from the face was characterized, the court continued, as a "type of beauty culture" in a case holding that using electrolysis was not the unlawful practice of medicine. Likewise, it has been held that the use of electrolysis to prevent growth of hair is similar to the work of a barber in removing hairs on a man's face. *People v. Lehrman*, 251 App. Div. 451, 296 N. Y. S. 580, affirmed 276 N. Y. 479, 12 N. E. (2d) 166; abstr. J. A. M. A. 110:839 (March 12) 1938.

In the opinion of the supreme court, the defendant conducted a beauty parlor without a permit in violation of the statute. The judgment of conviction was therefore affirmed.—*People v. Cohen* (N. Y.), 8 N. Y. S. (2d) 70.

1. In this respect the provisions of the Utah act correspond with those of the Uniform Narcotic Drug Act as formulated by the National Conference of Commissioners on Uniform Laws and enacted by many states.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Physiologic Control of Normal Human Gastric Secretory Curve. C. M. Wilhelmj and A. Sachs, Omaha.—p. 467.

Available Nutritional Iron in Molasses.—Harris and his co-workers estimated the availability of iron in molasses by the chemical (dipyridyl) procedure and by the biologic assay procedure. The molasses used in their tests was prepared from Louisiana sugar cane. Juice is extracted by pressure from crushed cane, heated, treated with sulfur and lime to precipitate some of the impurities, clarified and concentrated to 40 degrees Baume by heating at 63 F. This sugar cane syrup is boiled down still further to crystallize the sugar, and the resulting liquor was called sample A. A portion of this "first" molasses is diluted with cane juice and reworked to obtain another extraction of sugar. The resulting liquor was called sample B. The "second" molasses is diluted with water, reboiled to obtain another extraction of sugar and the resulting liquor was called sample C. The "available" iron by the chemical method in the three kinds of molasses was found to be 97, 85 and 54 per cent, respectively. By the biologic (rat) method the availability was slightly more than 90, 80 and 50 per cent, respectively. The dipyridyl procedure is acceptable for the determination of the availability of iron in molasses. Molasses is a rich and inexpensive source of available iron. The authors point out that, although the iron in high grade molasses is more available than that in a lower grade of molasses, the higher grade is not as rich in total available iron. For example, 100 Gm. of molasses A furnished slightly more than 3.1 mg. of "available" iron, whereas the same quantity of molasses B contained approximately 5.1 mg. of "available" iron. The results obtained with molasses C do not agree with those of Shackleton and McCance, who reported that the iron in black treacle is 100 per cent available. In the authors' experience only 54 per cent was available. It is not correct to base one's judgment of a food on its total iron

content, since iron availability varies with the kind of food. Molasses B is the type commonly used in the home; 85 per cent of its iron is available. Of the foods reputed to be excellent sources of iron, only liver compares favorably with molasses. Whipple and Robscheit-Robbins have listed chicken and beef liver, chicken gizzard, beef kidney, eggs, apricots and raisins as especially valuable in the treatment of anemia. From the authors' studies on these foods it appears that molasses is superior to all these foods in this respect and is, moreover, the most inexpensive food source of iron.

Significance of Bilirubin and Cholesterol in Feces.

The occasional presence of calcium bilirubinate, cholesterol or both in routine feces examinations led Boerner and his colleagues to examine 2,003 stools, in sixty-seven of which calcium bilirubinate, cholesterol crystals or both were found. In many instances the stools came from patients who were in the hospital for study of some condition unrelated to the biliary tract. Calcium bilirubinate alone was found in the feces in twenty-five cases and cholelithiasis was confirmed in eighteen. Of the remaining seven cases the diagnosis of cholelithiasis was not substantiated. Apart from cholelithiasis, two mechanisms may account for the presence of calcium bilirubin pigment in the bile and consequently in the feces: sudden release of noncalculous mechanical block of the main bile ducts or an increase in the serum bilirubin secondary to increased hemolysis may give rise to calcium bilirubinate in the bile in the absence of biliary disease. In a number of instances the first intimation of possible gallstone disease was the finding of calcium bilirubin pigment in the feces of a patient in whom that diagnosis was not suspected. Of fourteen cases in which cholesterol crystals alone were reported in the feces, there was only one in which the diagnosis of cholelithiasis was confirmed. Seven of the cases, however, were not studied for cholelithiasis.

Streptococcus Viridans Endocarditis Lenta.—Middleton and Burke present the clinical and pathologic features of eighty-eight cases of Streptococcus viridans endocarditis lenta which were observed at the Wisconsin General Hospital. They think that some of the details of the clinicopathologic analysis merit special emphasis. They adduce further evidence in support of a close relationship between congenital and rheumatic lesions of the heart and endocarditis lenta. Acute upper respiratory infections, rheumatic fever, infected abortion, dental extraction and massage for nonspecific prostatitis apparently served as precipitating factors in the development of certain cases of this condition. Contrary to the accepted opinion, congestive heart failure may attend or mask this condition. The clinical manifestations and course are varied and inconstant. After the

cardiac changes, particular attention was directed to its toxic and its embolic features. Splenic and renal changes, including embolism, were frequent. Mycotic aneurysms offered serious diagnostic problems. Cerebral accidents were not infrequent. Occasionally a mycotic aneurysm of a cerebral vessel may explain certain neurologic phenomena of this condition. Again the clinical picture may suggest thyrotoxicosis, and the unexplained elevation of the basal metabolic rate may add to the diagnostic confusion. This study offers material support to the importance of the diagnostic triad petechiae, splenomegaly and a positive blood culture for the *Streptococcus viridans*. Given the background of a congenital or a rheumatic heart lesion and a remittent fever, this triad offers the logical direction of attack. The prognosis of *Streptococcus viridans* endocarditis lenta is grave. Only inferential evidence of the pace of the decline is offered by the circulatory, renal, embolic, toxic, constitutional and hematologic reactions. Although remissions of varying durations and degrees are the rule, certain of these patients undergo a rapidly progressive decline. Attention is directed to the ominous significance of the euphoria that attends late remissions. This group included one instance of healed endocarditis lenta. The clinical activity apparently occurred at a period previous to the hospitalization. In the remaining eighty-seven cases all treatment was unavailing.

Effect of Sulfanilamide on Spermatogenesis.—Heckel and Hori say that the administration of sulfanilamide derivatives to man has been thought to influence spermatogenesis. To study this problem the authors analyzed the semen of eleven patients before and after sulfanilamide was given. They describe their method of examination and in a table they show the number of specimens examined, the total number of spermatozoa and the percentage alive before, during and after treatment; the time specimens were obtained in relation to the treatment and the duration of the treatment. The sulfanilamide was given by mouth up to a total of 40 grains (2.6 Gm.) daily, except when the drug was not tolerated, and then the dose was reduced or the patient was put on a rest period for two or three days. In contrast to other reports, these data indicate that in eleven cases there were no noteworthy effects on the total number or percentage of live spermatozoa from the use of sulfanilamide. Such variations as occurred in the spermatozoa counts during and after treatment were no greater than the variations which occurred before the drug was given.

Type Specific Immune Rabbit Serum in Pneumonia.—Callomon reports experiences with type specific antipneumococcus rabbit serum in forty-five cases. Included in this series are cases of pneumonia of types I, II, IV, V, VII and VIII. The only factor entering into their selection was the availability of a homologous immune serum at the time of their admission. In the majority of cases the product employed was unconcentrated. In a few of the more recent cases a concentrated preparation was administered. All cases reported showed roentgenographic evidence of consolidation and a positive blood culture or sputum in which the pneumococcus was the predominating organism. A history, physical examination, urine analysis, blood count, blood culture, sputum examination and roentgenogram of the chest were obtained on admission. Blood cultures were taken at two day intervals or more frequently when indicated. Identification of the type of pneumococcus present in the sputum was made by the Neufeld method and in many cases confirmed by passage through the mouse. Before treatment was instituted, all patients were given ophthalmic and intracutaneous tests for sensitivity to the specific serum which was to be used. The usual precautions, advisable in all serotherapy, were observed. When a positive intracutaneous test was associated with a negative ophthalmic test, the administration of serum was undertaken, but with more than the usual caution. All serum was given intravenously. At first, doses of 20,000 units were given at two hour intervals. Later this plan of treatment was altered, as the administration of larger doses seemed preferable in order to introduce the total dose in as short a time as possible. Following an initial dose of 20,000 units, one or more doses of 100,000 units were given until it was apparent that the disease was being brought under control. Subsequently, smaller doses were given as seemed indicated until recovery was complete. In several cases one injection of 100,000 units following the

initial dose of 20,000 units was sufficient to secure the desired result. Supplementary treatment consisted only of dietary regulation and symptomatic treatment, including oxygen administration, when indicated. Regarding the results obtained with this treatment, the author says that two deaths occurred in this series. Premature recovery by crisis or rapid lysis ensued in thirty-six cases. No serious serum reactions were observed.

Symptomatology of Oxyuriasis.—Brady and Wright made studies in 200 cases of oxyuriasis. This material included persons seeking treatment for known pinworm infestation, persons referred to them because of symptoms suggestive of oxyuriasis and persons in whom pinworms were detected by anal swab examinations made in the course of studies on the incidence of oxyuriasis. Comparative studies were made on two control groups. One group of seventy-two persons was negative for pinworms on examination by the swab method, but they lived in households together with infested subjects. A second group of twenty-one persons was negative for pinworm and lived in homes in which no member of the family was found infested. In each of the 200 cases of oxyuriasis the history was taken, a physical examination was made, a stool sample was examined for helminth ova, anal swabs were made, and in girls a vulvar swab was made. The opinion is expressed that symptoms may be caused by mechanical stimulation and irritation by the parasite, by allergic reactions, and by the transportation of organisms to places where they may become pathogenic. Many infested children showed gains in weight, improvement in color, and disappearance of dark circles under the eyes after treatment. There was an average eosinophil percentage of 5.1 in 144 pinworm cases compared to 3.7 in twenty-one children coming from households in which all persons were free from pinworms. There is too much deviation from the mean for these figures to assume statistical significance, but it is likely that there is a slight increase in eosinophil percentage in oxyuriasis. One case presented symptoms of nausea and vomiting that could not be attributed to causes other than the pinworm infestation. These symptoms disappeared when the pinworm infestation was eradicated. The authors found no proof that abdominal pain and oxyuriasis were directly related. Only one patient of the 200 had had an appendectomy. The appetite in many cases was much improved after treatment. It is believed that pinworms cause conscious sensation when moving on the rectal and anal mucosa but that no sensation is felt in the majority of cases after the pinworm has migrated onto the skin. Allergic reactions to pinworm products are probably associated with the marked sensation experienced by some few persons from skin migrations. Enuresis was not found to be more common in infested patients than in noninfested controls. Evidence is presented that a pinworm vaginitis may be much more frequent than it has been considered to be in the past. Restlessness and insomnia are symptoms occurring in pinworm cases. Restlessness in school may lead to scholastic difficulties. The feeling of shame that an impressionable child may have from the consciousness of having pinworms may have repercussions in the behavior of the child. Evidence to show that pinworms cause nervous irritability was inconclusive.

Impurities in Ether.—Bradshaw reports a case in which death in convulsions occurred during the administration of nitrous oxide-oxygen-ether. Some blood was obtained for examination before death. The blood showed an oxygen content of 6.9, oxygen capacity of 14.6, saturation of 47.3 and a carbon dioxide content of 61 volumes per cent. The concentration of sugar was 400 mg. per hundred cubic centimeters of blood (intravenous dextrose was being administered). The ether was analyzed and showed aldehyde present, 1:50,000 in two samples. No other impurities were found. Although 100 per cent oxygen was given for a period of ten minutes the cyanosis became greater and the convulsions continued. The oxygen content and capacity of the venous blood were low, with a low saturation. The carbon dioxide content was within normal limits. Excess carbon dioxide, hypoglycemia and lack of preoperative medication have been mentioned as causes of these convulsions. However, none of these conditions could have been active in this case. The only positive observation was a low oxygen content of the venous blood despite the administration of 100 per cent oxygen.

Appendicitis Complicated by General Peritonitis.—Williamson and Rankin treated thirty-two cases of appendicitis complicated by general peritonitis without a fatality. They attribute this result to the immediate removal of the appendix, after a reasonably brief period of preoperative preparation. Rapid evacuation of the septic material was secured by placing the patient in the ventral position. This rapid elimination of irritating material also tends to prevent postoperative adhesions and related postoperative complications. They prevented sepsis in the abdominal wound by leaving the wound open. Anaerobic bacteria cannot grow in air. If this factor were taken into consideration in the treatment of general peritonitis complicating appendicitis, it is doubtful that there would be need for bacterins, serobacterins, vaccines and the like against anaerobic bacteria. Thus the open wound prevents sepsis in abdominal wounds. Paralytic ileus is treated mainly by prevention. The ventral position aids considerably. The efficacy of prostigmine for this purpose has been demonstrated. This drug maintains the muscular tone of the intestine by preventing parasympathetic paralysis. In large doses it is a parasympathetic stimulant. In short, the peritoneum was closed down to the drains, the fascia and skin were left open and the wound was packed with gauze saturated with tincture of mercuric iodine, azochloramide or similar antiseptic. Deep through and through retention sutures were put in but left loose in order to pull the edges of the wound together gradually as the infection disappeared. When the patient was returned from the operating room he was immediately put on his abdomen and the head of the bed was elevated from 8 to 12 inches. Routine treatment consisted in hypodermoclysis of saline and dextrose solution and saline solution intravenously. An ampule of prostigmine was given every four hours and morphine was used for pain. Contrary to expectations the patients complained of little discomfort because of the position. The dressings were quickly saturated with the drainage from

the abdomen, necessitating frequent changing during the first twenty-four hours. The amount of discharge by far exceeded that of patients placed in the Fowler or other positions. This, because of rapid elimination of toxic material, undoubtedly accounted for the rapid drop in the temperature and pulse rate. As soon as they were tolerated, water and then liquids were given by mouth; after thirty-six to forty-eight hours the patient was put on his back. All patients were discharged from the hospital well after an average stay of 20.9 days and the wounds were healed, with the exception in a few cases of a small area at the site of the drains.

Simplified Technic for Administering Old Arsphenamine: Report on 16,943 Injections Given at Vanderbilt Clinic. A. B. Cannon, New York.—p. 621.

Postarsphenamine Jaundice.—Since hepatitis is difficult to reproduce experimentally, its clinical treatment is based on empirical experience and therefore Soffer points out that the prevention and treatment of postarsphenamine jaundice assume increasing importance. When it is considered that from 5 to 10 per cent of the general adult population has syphilis, that a considerable number of this group is receiving antisyphilitic treatment and that in 1 per cent of this treated group jaundice will develop with a mortality rate varying from 1 to 6 per cent, there is reason for concern as to the proper methods of treatment. From a review of the clinical and experimental data presented in the literature concerning the treatment of arsphenamine jaundice it is seen that a high carbohydrate diet is well accepted as an important therapeutic measure. Such diets should consist of from 400 to 600 Gm. of carbohydrates daily. This should be divided into five or six feedings. As the sugars fructose and dextrose are most readily converted into glycogen by the liver, foods made up of these carbohydrates should be used. Thus the most desirable are cane sugar, which is hydrolyzed into dextrose; honey, which is mostly dextrose and fructose; and fruit juices. When the amount of carbohydrate taken orally is inadequate, diets should be supplemented by a constant intravenous drip of a 5 per cent solution of dextrose. Insulin is indicated only when glycosuria is present. The use of choleragogues and cholcretics in the treatment of arsphenamine jaundice is unsound.

Sulfanilamide for Chancroid.—Greenblatt and Sanderson have used sulfanilamide in the treatment of thirty-three cases of chancroid disease. The doses varied in individual cases, the average being from 400 to 500 grains (26 to 32.5 Gm.) of sulfanilamide. The by-effects were nausea, anorexia, dizziness and cyanosis. The twenty-seven ambulatory patients were usually given from twenty-five to forty tablets of sulfanilamide at a time with instructions for medication and to return every few days. Treatment was discontinued in one case because a rash developed, in two because of excessive vomiting and in one because of cyanosis. With cessation of treatment the untoward effects abated. Dizziness was the most frequent complaint, but treatment was never discontinued because of it. Surgical procedures other than aspiration of buboes were not performed. The therapeutic results, for the greater part, were so consistently good that the drug is regarded as a specific. The previously reported results of the British and American investigators are substantiated. Sulfanilamide proved more efficient than any of the standard methods in vogue. It succeeded in some cases in which vaccine therapy had failed.

Coccidioidal Granuloma.—Theoretically, the ideal treatment of infectious diseases seems to be the administration of immunogenic antigens capable of activating the tissues and fluids to production of immune bodies. With this thought in mind, Jacobson decided to give vaccine treatment a trial in the management of coccidioidal disease. Since 1936 he has treated twenty-four cases of coccidioidal infection in its various clinical manifestations by this method. The character, extent of involvement and clinical course of the infection varied considerably. For the most part the clinical picture at the commencement of treatment was of the subacute variety. Evidence of past or present pulmonary involvement was present in the majority of cases. Next in frequency was involvement of the cutaneous-subcutaneous system, either as a primary manifestation or secondary to pulmonary or other systemic or structural coccidioidal disease. Involvement of bone was present in about 30 per cent of the cases. The aim of all therapeutic efforts was the raising of the patients' level of resistance to the existing infection. Accordingly, all febrile patients were kept in bed at complete rest. Nutritious and adequate diet, sunshine and fresh air played a definite part in the therapeutic regimen. Halibut liver oil with viosterol was given to all patients, and those seriously ill received injections of ascorbic acid daily or on alternate days. Anemic, dehydrated and undernourished patients also received blood transfusions, infusions of dextrose and parenteral injections of liver extract, according to clinical indications. Injections of vaccine constituted the specific part of the treatment. The vaccine was at first given subcutaneously, but later it was administered by the intravenous route. The standard initial dose has been 0.05 cc., and each succeeding injection has been increased by 0.05 cc. at intervals of from eight to fourteen days. In instances of unduly severe constitutional reaction, the dose of the succeeding injection was not increased and the interval was lengthened. A course consisted of from twelve to fifteen injections. Most patients received two or more courses of injections, punctuated by intervals of rest of from six to eight weeks. Five of the patients are still under treatment. Three are ambulatory and engaged productively but come to the office for injections of vaccine at regular intervals. All others have been discharged as fully recovered or are reporting regularly for observation. Two patients, one with widespread meningeal involvement and another suffering from the acute fulminating type of the disease, died. Specific immunogenic therapy is a rational procedure theoretically and has proved its worth clinically.

Abscesses of Sweat Glands.—Tachau reports 107 cases of sweat gland abscesses of the axilla. In 26 per cent a symmetrical involvement of both axillas was noted. In the others only the right or the left axilla was infected. In ten cases the abscess formation must be considered as a complication of local or generalized inflammatory dermatoses (contact dermatitis, eczema, epidermophytosis, erythrasma or arspenamine dermatitis). Two patients were observed with abscesses of the sweat glands secondary to scabies and furunculosis, and another with Bockhart's folliculitis. One patient had retrograde lymphangitis extending down the arm. In other regions the author never observed a coincidental or successive involvement of many apocrine glands. Thus, only single abscesses running an acute course were occasionally observed around the nipple, on the pubic area, on the labia majora and around the anus. The infection of the apocrine glands starts from the outside. Local

inflammatory processes, irritation by depilatories or shaving or the friction of tight clothing often favors the infection. They should never be considered as the actual causes. According to present knowledge, abscesses of the sweat glands are due to infection with *Staphylococcus pyogenes aureus* (and perhaps *albus* or *citreus*). The cultivation of streptococci or other germs from the abscesses does not prove their etiologic significance. The prognosis of abscesses of the apocrine glands is always favorable. The treatment of a single abscess consists in local application of dressings with a mild ointment (3 per cent of boric acid in petrolatum) or topovaccines, such as Sherman's mixed antiviral cream. Wet applications are not advisable, since they favor maceration and may give rise to the formation of new abscesses. As soon as softening occurs, a small incision is made for evacuating the pus. This is followed instantly by a quick and complete cure. Even in the axilla this simple treatment succeeds in uncomplicated cases. When the abscesses multiply and the patient is disabled, treatment with roentgen rays is the method of choice. In many cases a small dose suffices to give relief (from 100 to 120 roentgens, 70 to 80 kilovolts, filtered by 3 mm. aluminum; focal skin distance, from 25 to 30 cm.; diameter, from 10 to 15 cm.). Two or three days later the pain is usually gone. For more resistant lesions this dose must be repeated once or twice at intervals of ten days. Of thirty-seven patients treated since 1931 according to this technique, eight were cured after only one dose of from 100 to 120 roentgens; ten were cured after two exposures, or from 200 to 240 roentgens, while seventeen needed three exposures, or from 300 to 360 roentgens. In only two cases did considerable residual infiltrations or sinuses make it necessary to repeat the x-ray cycle after an interval of six or more weeks. Recurrences were never seen in this series.

Squamous Metaplasia and Prostatic Infarction.—Squamous cell metaplasia and infarcts of the prostate have been described independently by several authors but Culp believes that the frequent coexistence of these two pathologic processes has been overlooked. In a recent routine study of a prostate removed by operation, islands of squamous epithelium were observed along the margins of three infarcts. The provisional diagnosis was early squamous cell carcinoma. Further study of the remainder of the prostate showed only typical glandular hyperplasia. Eight additional prostatic infarcts, occurring in seven different cases, were studied and in each instance similar histologic changes were seen, limited to the periphery of the infarcted areas. The uniformity of these observations indicates that benign metaplasia frequently is associated with prostatic infarction and may be misinterpreted as carcinoma.

Angina Pectoris of Psychogenic Origin.—Master and his associates point out that generally the anginal syndrome is caused by coronary artery disease and can be differentiated from a functional syndrome by the type of pain. In the organic type the pain is nearly always substernal and occurs as a rule after exertion, meals or excitement, whereas in the functional type the pain is usually over the precordium or nipple, often lasts longer and is not related to effort. In the main, this differentiation holds true but that angina of psychogenic origin may also be substernal and come on with exertion is illustrated by the case that they report. Although the anginal syndrome for which the patient (29 years of age) presented himself was characteristic of coronary artery disease and at one time was actually diagnosed coronary occlusion by a cardiologist, after four years it became obvious that it was merely the first symptom in what later became a well established neurotic complex. There certainly was no organic heart disease, for, after four years, the physical examination and all laboratory tests are normal. The authors are cognizant of the claim of some authors that angina pectoris due to coronary artery disease may be present in the absence of confirmatory evidence of any kind. However, they believe that this is rare if all tests are considered, particularly after a period of several years of observation. While the physical examination of the heart, fluoroscopy, electrocardiogram, exercise tolerance, and vital capacity may individually remain normal, it is improbable that all of these will do so. In the mechanism of pain in coronary artery disease a nervous mechanism is important, as even when organic coronary artery disease is present the frequency and severity of the anginal syndrome are greatly influenced by mental and emotional factors or, in the words of Heberden, "by passionate affections of the mind." Two patients with similar degrees of coronary artery disease may suffer pain of different severity, depending on the psychic makeup of each patient. Psychiatrists have emphasized the importance of the heart as the "specific sense organ of anxiety" and the close interrelation of the brain with the innervation of the heart. And, indeed, precordial pain is often the major symptom of a neurosis without organic basis. While the pain of organic heart disease is usually related to effort, not infrequently such an association is lacking. And pain of psychogenic origin may come on with effort occasionally. Exertion produces changes in pulse rate and contraction of the heart which in susceptible persons may cause sensations of pain, as was true of the patient presented. It is thus sometimes impossible to differentiate an anginal syndrome of organic origin from a functional one by the type of pain and its relation to effort.

Course of Traumatic Psychoses.—In order to ascertain the prognosis and ultimate fate with regard to patients who became psychotic following head injury, Hoch and Davidoff investigated the records of 251 consecutive cases of traumatic

psychoses. The preponderance of cases in males (205) is due to the more frequent exposure of men to trauma and in part to occupational causes. Many of the traumatic psychoses were not psychoses due purely to the trauma alone but were associated with other conditions. Of the total number of cases 117 were complicated, in order of their frequency, by alcohol, cerebral arteriosclerosis, senility, neurosyphilis and other miscellaneous conditions such as mental deficiency and epilepsy. These complicating factors are of prognostic importance, as the prognosis is graver in these cases than in those in which no complicating factor exists. Senility and cerebral arteriosclerosis offer the gravest prognosis. The outlook is possibly rendered less hopeful in those cases in which there is an antecedent disturbance to the cerebral circulation. Besides the foregoing complicating concomitants there is another factor which has not been stressed sufficiently in relation to the traumatic psychosis group. An important prognostic determinant is the previous personality organization of the patient who has sustained an injury to the head. Of the schizoid personalities, 75 per cent were definitely unimproved. For patients more of the syntoid type, the prognosis was far better and the percentage of recovery and improvement greater. The ratio of unimprovement in the introvert type as compared to the extrovert type was approximately 2:1. Hallucinations and delusions were present in many cases but were not accompanied by neurologic phenomena characteristic of cortical or subcortical lesions. In the absence of these signs, it would be very difficult to attempt any localization of these psychic manifestations. While it is commonly known that hallucinations and delusions may occur in transitory form in any organic psychosis during the delirious state, they tend to disappear in concomitance with the improvement or recovery of a patient from the confusion or clouded state. In the traumatic psychoses, however, an important feature has been that a patient with a schizoid or introvert makeup regains his mnemonic functions and the approximate lucidity of his prepsychotic intellectual state but unharmoniously retains the hallucinations and delusions. Other factors no doubt enter into the clinical picture of the more protracted cases. In addition to the stresses and strains to which the patient is exposed and his reaction to change and thwartings, to financial and family situations, to occupation and to the important questions of compensation and litigation, attention should be focused on the previous personality makeup and what bearing this has on how the individual reacts to the situation. Also it is likely that study of the personality would greatly aid in the understanding of traumatic neuroses.

Public Health Hazard of Carbon Monoxide.—The hazards of carbon monoxide to public health are discussed by Franklin, who states that ordinarily it does not appear in nature but results almost entirely from incomplete oxidation of carboniferous material. It has been reported to have been formed in large amounts during severe electrical storms and to have been produced by growing kelp. It is present when buildings burn, is produced in lime, brick and charcoal kilns, is present following explosions and fires in mines and it is also produced on detonation of high explosives. In the laboratory it is produced by heating formic or oxalic acid with sulfuric acid. It is found in smoke and in compartments which have been painted with oil paints and sealed. It has even been reported formed from burning cigarettes. About 16 per cent of coal gas is carbon monoxide, 28 per cent of blast furnace stack gas, from 1 to 8 per cent of mine air after dust explosions is carbon monoxide and about 7 per cent of the exhaust from automobile motors. The author points out that 5 per cent of the cars tested on the highways by Van Deventer showed a dangerous concentration (0.03 per cent or more) of carbon monoxide in the air that the driver breathed. The public should be educated on all phases of the hazard, and especially those likely to come in contact with a high concentration of carbon monoxide, such as firemen and policemen. It should be able to recognize symptoms, know the incidence and be able to give first aid. Statistics should be compiled and made available to the public. Methods of accurately detecting injurious amounts of the gas in air should be developed and the public educated in detecting the gas in homes, garages, motor cars and other places. A possible solution of this point could be that the gas companies when installing gas in a home or apartment be required to supply each patron with a piece of apparatus for detecting leaking gas. There should be more experimentation to determine better methods of treatment. Legislation should be enacted for the elimination of the hazard in factories, public garages, mines and wherever there are employees. Such legislation should be supplemented by regular inspection under public health jurisdiction.

Blindness in Adults.—In discussing the prevention of blindness in adults, McLeod examines a typical set of statistics, the tabulation of 11,852 cases of blindness in Pennsylvania. When all congenital anomalies, for which treatment is of little avail in any case, traumatism, all external infections (except gonorrheal conjunctivitis but excluding ophthalmia neonatorum) and all predominantly juvenile diseases are excluded a total of 87 cases remains. If ulcerative keratitis (194) is also eliminated on the assumption that all cases were due to external infection and all cases of senile cataract (2,666) there remain 5,919 cases of blindness due to general disease. It is questionable if senile cataract should be omitted, since under this diagnosis we classified all cases of diabetes in which the cataracts develop after the age of 50 and since complete blindness with cataract depends on some retrolenticular disturbance. Breaking down this figure of 5,919 cases due to general disease gives the following incidence: uveitis (all causes) 25.3 per cent, choroiditis 8.2 per cent, chronic glaucoma 24.8 per cent, acute glaucoma 1.9 per cent, vascular diseases (including diabetic and nephritic retinitis) 10.6 per cent, optic atrophy 20.3 per cent and neuritis 5 per cent. This group makes up a total of 96.1 per cent of the 5,919 cases. If from this group glaucoma is excluded there is still 69.4 per cent of these cases (approximately 35 per cent of the total number) the origin of which lies in some systemic condition with focal infection, vascular disease, syphilis and tuberculosis predominating. The importance of watching for early optic nerve changes in syphilis cannot be too strongly emphasized. Here, as in glaucoma, the disease may progress to a dangerous point before visual acuity is noticeably diminished particularly if the patient is not too intelligent. Recognition of the possible causal agents of certain eye conditions, notably iritis and uveitis, is of great help in searching for the probable factor (usually focal infection or syphilis) responsible for them. Knowledge of the ophthalmologic pictures in chronic disease involving the vascular systems is of help in formulating the diagnosis and prognosis of these conditions. Nothing can be done about them by local measures and their treatment resolve itself into treatment of the underlying disease.

Meningitis Due to Micrococcus Tetragenus.—Crisafulli reports a case of meningitis due to *Micrococcus tetragenus* with recovery. A lumbar puncture was done, and the morphology, the staining reaction and the cultural characteristics of the organisms were consistent with those of *Micrococcus tetragenus*. Ordinarily this organism is found in the nose and throat, where it is not considered to be pathogenic. Although this patient gave no history of infection of the upper part of the respiratory tract, it is likely that the organism gained entrance to the central nervous system from the right ethmoid sinus. Therefore, one should carefully examine the upper part of the respiratory tract for possible foci of infection in these cases. A blood culture was not done on the day of admission. Although one taken seven days later was negative, the patient had already been taking sulfanilamide for five days. The author is of the opinion that in this type of meningitis one is not deal-

ing with a virulent type of organism and that if the patient can be kept alive until he has manufactured enough immune bodies he will recover. Were the author again faced with the same situation, he states that he should look for possible foci of infection in the upper part of the respiratory tract, give supportive treatment, do a lumbar puncture as often as indicated by the patient's condition and give sulfanilamide in adequate doses.

Rabbit Serum for Pneumonia.—Loughlin and his colleagues used unconcentrated and refined rabbit antipneumococcus serum in the treatment of forty-one patients with pneumonia due to the type V pneumococcus, forty-six due to the type VII organism and thirty-eight with type VIII pneumonia. In the first group the pneumonia had been present for an average of ninety hours, with extremes of twenty-six and 192 hours, before rabbit serum was administered. Nine patients had bacteremia when first seen. The average dose of rabbit serum was 290,000 units, and crisis occurred in an average of fourteen hours. Forty patients recovered, and one died. This patient, who was not given serum until 120 hours after onset, died apparently during a thyroid crisis. Thirty-two patients, six of whom had bacteremia, were successfully treated with one dose. In these patients, crisis occurred in an average of eight and one half hours; the average single dose was 246,000 units. The blood stream was sterilized in every instance after the administration of the projected dose. Serum sickness developed in eleven patients. In the patients with pneumonia due to pneumococcus type VII the disease had been present for an average of eighty-three hours, with extremes of twenty and 192 hours, before rabbit serum was administered. Sixteen patients had bacteremia on admission. The average amount of rabbit serum given was 340,000 units. Crisis occurred in an average of fifteen hours. Forty-four patients recovered and two died. In these two fatal cases a severe bacteremia was found and serum therapy was delayed until ninety-six and 144 hours, respectively. One patient was moribund on admission, had pulmonary edema and died

within twelve hours after treatment with serum was begun. Thirty-six patients, seven of whom had bacteremia, were successfully treated with one dose. In these patients, crisis occurred in an average of nine and one half hours; the average single successful dose was 279,000 units. The blood stream was sterilized in every instance after the projected dose. Serum sickness developed in nine patients. In the remaining thirty-eight patients the type VIII pneumonia had been present for an average of seventy-nine and one half hours, with extremes of fifteen and 336 hours, before rabbit serum was administered. Twelve patients had bacteremia on admission. The average amount of rabbit serum given was 300,000 units. Crisis occurred in an average of twelve hours. All the patients recovered. Thirty-four patients, of whom nine had bacteremia, were successfully treated with one dose. In these patients, crisis occurred in an average of ten hours; the average single successful dose was 269,000 units. The blood stream was sterilized in every instance after the administration of the projected dose. Serum sickness developed in nine patients. This generally consisted of fever, urticaria and arthritis. These symptoms usually were mild or moderate in severity, although in a few instances a rather severe arthritis was noted. There were no instances of lymphadenitis. The authors conclude that the effectiveness of any therapy in pneumonia depends on (1) the rapidity with which it can destroy the pneumococci in the tissues of the lung and in the blood stream, (2) how quickly it can neutralize the toxins and reduce the toxemia, (3) the rapidity with which it can supply pneumococcus antibodies or stimulate their formation and (4) the absence of untoward reactions that would endanger the patient's life. They find that the homologous unconcentrated and refined rabbit antipneumococcus serum fulfills these requirements in the treatment of types V, VII and VIII pneumonia.

Nonpollen Factors Simulating Seasonal Allergy.—Prince discusses some of the so-called miscellaneous factors that have been so important in several of his cases that they must be regarded as the primary excitants in what otherwise appeared to be true pollinosis; in other instances they have assumed equal importance with pollens in determining seasonal symptoms. As a basis for this report he has selected 150 patients with respiratory allergy studied during the past two years. Of these, ninety-two have symptoms in one or more well defined seasons and fifty-eight have definite yearly seasonal exacerbations. Symptoms of this group are distributed as follows: asthma thirty-eight, hay fever seventy-five and hay fever and asthma thirty-seven. Grass is the most important seasonal inhalant factor (91 per cent) encountered in the spring, followed by trees with 58 per cent. But also 54 per cent of the spring patients reacted to air-borne molds, 71 per cent to danders, 83 per cent to house dust and 25 per cent to orris root, while only 5 per cent reacted to pyrethrum. Similarly 92 per cent of summer patients reacted to grass, and almost as many to house dust (88 per cent) and danders (66 per cent) as in the spring group. However, the percentage of mold reactions is 75, compared with 54 for the spring; orris root is about the same (28 per cent) and pyrethrum is increased to 17 per cent. In the fall group 90 per cent reacted to ragweed, 72 per cent to grass and 26 per cent to chenopodiales; to other factors, reactions occurred as follows: dust 90 per cent, molds 68 per cent, danders 62 per cent, orris root 21 per cent and pyrethrum 7 per cent. In the winter only 35 per cent reacted to pollens (trees), while 98 per cent were sensitive to house dust; 77 per cent reacted to danders, 66 per cent to molds, 35 per cent to orris root and 14 per cent to pyrethrum. In none of the four major seasons, then, can pollens be considered as the entire cause of symptoms. Therefore more attention should be given nonpollen factors which may complicate what appear to be simple cases of seasonal allergy.

*Role of Vitamin A Deficiency in Etiology of Renal Calculus. K. Long and L. N. Pyrah.—p. 216.

Pycnographic Reactions. T. Moore.—p. 233.

Vitamin A Deficiency and Renal Calculus.—Long and Pyrah studied twenty-five cases of upper urinary lithiasis for vitamin A deficiency together with sixty-five control subjects drawn from healthy people of different economic grades of society. Whereas 75 per cent of the control subjects gave a normal dark adaptation reading, only 36 per cent of the patients who had suffered from urinary lithiasis showed normality. The reading of the remaining 25 per cent of the normal individuals fell just short of the required standard of normality. There were no definitely subnormal readings, whereas among the 64 per cent of the patients suffering from urinary lithiasis 24 per cent were slightly subnormal and 40 per cent were definitely subnormal. After concentrated vitamin A therapy (13,000 units daily for four or five weeks) given to selected patients, 42 per cent gave normal and 58 per cent subnormal readings. One or two patients showed a slight improvement, but this proportion was small and 33 per cent remained definitely subnormal. Therefore dietary deficiencies alone cannot account for the differences in readings between the selected patients and the control subjects, and it would certainly appear from the results that a low body reserve of vitamin A is commoner among patients who had had a urinary calculus even at some interval after operation than among other ordinary healthy members of the community. The results are somewhat similar to those of Ezickson and Feldman, and of Higgins, although the authors state they are not so definite. Too much importance must not be attributed to the vitamin A deficiency found among the 40 per cent of the patients with urinary lithiasis. The general evidence and the results point to this deficiency as only a contributory part in the etiology of urinary lithiasis. At the same time it is interesting that a course of vitamin A therapy had such poor results in raising the vitamin A reserves among the patients, when it is known that such therapy among people who are suffering from dietary deficiencies can usually effect improvement in two or three weeks. Various explanations have been advanced to explain these facts. The deficiency might be explained by excretion of vitamin A in the urine. The deficiency and its apparent inability to be remedied by the oral administration of the vitamin may be perhaps the result and not the cause of the disease and may be related to impairment of kidney function which may be found in some of these patients. This hypothesis the authors believe is worth further investigation. Those selected patients with a short clinical history and no evidence of derangement of kidney function and those with either slight or no infection of the urine before operation usually gave normal readings. On the other hand, those with a long clinical history with its possible effects on the kidney tissue or those who presented evidence of long standing chronic urinary infections, with blood, albumin and bacteria in the urine before operation, generally gave definitely subnormal readings. If this hypothesis were true, it would also provide an explanation for the normal dark adaptation reading of some of the patients

and for the lack of improvement among the subnormal ones after vitamin A therapy. The urine of eight definitely subnormal patients was tested for the presence or absence of vitamin A and also any obvious evidence of impaired kidney function was observed. This investigation failed to show any definite evidence of gross renal damage and in no case was vitamin A to be found in the urine. It seems, therefore, that loss of vitamin A by excretion in the urine cannot account for the low vitamin A reserves found in these cases of renal calculi, and it would appear that the deficiency is more likely to be correlated, as already postulated by Jeghers and Moore, with some defect in the metabolism of the patient or with an inability to absorb the vitamin from the diet. Nevertheless, it is the authors' intention to continue with these investigations on similar patients before operation so that the degree of the importance of this vitamin A deficiency in urinary lithiasis can be interpreted more exactly.

Thiamin Chloride for Trigeminal Neuralgia.—Seven cases of trigeminal neuralgia have been treated with thiamin chloride and Bakhsh states that in six of these improvement ranged from 100 (in four) to 30 per cent. The patient who did not respond to this therapy gave a history of syphilis and although the Wassermann reaction was negative he was given a course of mercuric and iodides by mouth without any relief. The four patients who were completely relieved received 160, 210, 84 and 90 mg. of thiamin chloride each and in all of them improvement commenced promptly and in two it was complete when only 50 mg. of the vitamin had been given, although treatment was continued for a few days more. The author has also used thiamin chloride in doses of 10 mg. daily in a case of early disseminated sclerosis for more than one month without the slightest improvement. In another case of diabetic polyneuritis, oral and parenteral administration of from 10 to 20 mg. of the vitamin without insulin for one month produced no effect on the sensory changes; in fact, the patient complained of an exaggeration of tingling and burning sensations in the hands and feet. When his urine became sugar free after insulin therapy he was relieved within a few days. Two cases of arsenical neuritis were uninfluenced by prolonged thiamin chloride therapy, although similar dosage in four cases of polyneuritis of unknown origin produced satisfactory results and the improvement was noticeable in the first week of treatment. One patient with nerve deafness did not respond to six weeks of treatment given by mouth as well by injection. The clinical data are too scanty to evaluate its efficacy in all the diseases for which it is advocated but it seems to be of particular value in many forms of polyneuritis. Whether the action of the vitamin is due to its replacing any deficiency or to some other action is not quite clear yet.

Ionizable Iron in Milk.—Pal determined the available iron in ten different samples of cow's milk from a dairy, a local milkman and a local market and two mixed samples of mother's milk. Almost all the iron present in milk is in available form.

The average available or ionizable iron content in the cow's milk was 0.635 mg. per hundred cubic centimeters of milk. This is almost equal to the total iron present in the samples. The mean figure for ionizable iron in mother's milk was also almost the same as the total iron present and was found to be 0.625 mg. per hundred cubic centimeters of mother's milk.

Postoperative Thrombosis and Embolism.—Pilcher says that a careful study has been made at the University College Hospital in London for cases of thrombosis and embolism. The records of the decade from 1929 to 1938 have been analyzed to show the interrelation of thrombosis and embolism, and the mortality of the latter. Prophylaxis was tried in the series presented, but no specific treatment except embolectomy in one case. Regarding the criteria of diagnosis the author says that in both thrombosis and embolism there is a rise of temperature. In simple thrombosis the rise is seldom of more than 1.5 degrees F., but when embolism occurs the temperature rises higher. The rise of temperature in a case of embolism often precedes the symptoms and may be presumed to be due to undetected thrombosis. The signs on which thrombosis is diagnosed are delayed cooling on exposure, pain and tenderness, edema, slight cyanosis and fullness of superficial veins. Of these the most constant are tenderness and delayed cooling; these in conjunction with a rise of temperature would be regarded as evidence of thrombosis. The signs of thrombosis enumerated were not all present in every case. In the diagnosis of embolism little importance is attached to the presence of recognized thrombosis, and, in fact, in the majority of cases no thrombosis was found. Unless, therefore, gross errors are made in the diagnosis of embolism, it must be accepted that many cases of thrombosis are not diagnosed. The fact that thrombosis may be latent makes it difficult to assess its risks on the evidence of diagnosed cases. Pulmonary embolism in addition to fever has three important features: pain, hemoptysis and signs of pleurisy or consolidation. The 261 cases of thrombosis and embolism that are discussed here are analyzed in several tables. The first table lists ninety-eight cases of femoral or iliac thrombosis only, forty-three cases of thrombosis with nonfatal embolism, sixty-eight cases of nonfatal embolism with recognized thrombosis, forty-four cases of fatal embolism and eight cases of thrombosis or embolism which were diagnosed in life but in which death resulted from other causes. The second table analyzes the material from the point of view of association of thrombosis and embolism and the third table lists the mortality rates. The mortality rate of the whole series was 16.8 per cent. The mortality rate of the first attack of embolism was 21.6 per cent. The total mortality rate of embolism was 28 per cent. Fatal embolism followed 4.6 per cent of diagnosed thromboses and 8.1 per cent of diagnosed nonfatal embolisms. This difference is not statistically significant. In the majority of nonfatal embolisms no evidence of thrombosis was found. The majority of fatal embolisms were unexpected. Thrombosis diagnosed in life is commoner on the left side than the right. This is the reverse of the observations in a large postmortem series of fatal embolisms.

Iron and Hemoglobin During Pregnancy.—Widdowson studied the hemoglobin levels of pregnant women before, during and after periods of therapeutic medication with iron. Hemoglobin determinations were made by the Haldane method of 100 women, all of whom were twenty weeks' pregnant or less, attending the antepartum department of King's College Hospital, London. The determinations were repeated a month later. Then half the women (those attending on Wednesdays) were prescribed 1,000 mg. of iron, as ferric ammonium citrate or ferrum reductum, daily for six weeks. The level of hemoglobin

in the capillary blood was determined at fortnightly intervals. The administration of iron was then stopped and the hemoglobin estimated fortnightly until a week after delivery. The other women (attending on Tuesdays) were given no medicine, and their hemoglobin levels were observed at monthly intervals until delivery and again a week later. In both groups an estimation was always made within twenty-four hours after delivery. At the end of the experiment it was decided not to consider (1) women whose babies were born before the thirty-sixth week, (2) women who had taken the last dose of iron within eight weeks of delivery and (3) women in the experimental group who had not taken the prescribed iron. After these omissions thirty-one women were left in the "iron" group and forty-four in the control group. In the control series the characteristic response was a tendency to fall steadily throughout pregnancy and to rise sharply after delivery. The cause of the fall, although possibly in some cases the result of a true deficiency of iron, is probably due largely to a rise in the volume of plasma unaccompanied by a corresponding rise in the number of circulating red blood cells. The responses of the experimental group are much more complicated than those of the control because, besides the effects of pregnancy and delivery common to the two groups, two further stimuli were in operation: (1) the administration of iron and (2) the cessation of its administration. The response to iron was not an instantaneous increase in all the women's hemoglobin concentrations. A few of the hemoglobin curves continued to fall, as though iron had not been given at all; several showed a break in the fall but no real rise, and some of them rose. The cessation of administration of iron led almost always to a fall in the hemoglobin level of those women in whom its administration had initiated a rise. In the discussion the author points out that, whereas the administration of iron has been shown by others to check the fall of hemoglobin during pregnancy, the fall after the administration has been stopped is a new observation and one which is difficult to explain. The tentative explanation offered by him is that one of the many factors regulating the level of hemoglobin in the circulation is the amount of iron in the plasma; the more there is, the more active the marrow cells become. When iron is not being administered, the amount of iron in the plasma is maintained at a low constant level by the high capacity of the storage organs. The administration of iron, however, temporarily raises the plasma iron, which stimulates the marrow to greater activity. It will be noted that this theory emphasizes the amount of iron in the plasma rather than the amount in the body as the regulator of marrow activity. The problem arises: Does the raising of a person's hemoglobin with massive doses of iron prove that the person was in need of iron; i. e., in a pathologic state? It might reasonably be held that, if the hemoglobin fell to its original level when the iron was discontinued, no pathologic state had been disclosed. Against this view must be set the weight of clinical opinion, which has pronounced definitely in favor of raising the hemoglobins of babies and pregnant women.

Familial Hepatitis.—Parsons reports familial hepatitis in a family of nine children. Two of the children are alive and well, two are alive and have hepatic enlargement, four have died from hepatic failure and one has died probably of some other cause. No member of the family suffered from icterus neonatorum and in no case has there been any suggestion of retardation of growth. Both parents are alive and well. They

have not suffered from relevant illnesses in the past and, so far as can be ascertained, there is no history of hepatic dysfunction on either side. Although necropsies were done on only two members of this family, the appearances observed are common to those of patients dying of cholemia. The picture in one case was that of a perlobular cirrhosis and in the other of a multilobular cirrhosis, but in each case it appeared that an acute hepatic necrosis was superimposed on a chronic hepatitis. No satisfactory evidence was obtained of the ingestion of any substance known to provoke hepatic damage. The incidence of the cases occurring over a period of twenty-two years is against this view. The occurrence of choreiform movements for fourteen months before death in one case and the fact that the disease manifested itself in the second decade of life indicates that the possible diagnosis of hepatolenticular degeneration cannot lightly be dismissed, particularly as the changes in the brain in this condition are not always visible to the naked eye on postmortem examination and that they are sometimes elusive on microscopic examination. The presence of cirrhosis of the perlobular type, the absence of significant changes in the brain and the occurrence of unilateral movements diagnosed as hysterical are, on the whole, not in harmony with a diagnosis of hepatolenticular degeneration, and it would seem that the family should be regarded as an example of familial hepatitis.

Methemalbumin in Man.—Methemalbumin in man, according to Fairley, is formed from extracorporeal hemoglobin when blood is destroyed in large quantities and remains in the circulation for a sufficient time. During the extracellular catabolism of hemoglobin, the molecule is split into globin and haem. The haem is oxidized to hematin, which promptly unites with serum albumin to form methemalbumin, the latter not passing through the kidney and never appearing in the urine. Recent work by Rimington indicates that hematin injected intravenously produces an increased porphyrin excretion in the feces. It appears that, like bilirubin, methemalbumin is disposed of by way of the liver and would be present in greater concentration in the circulation when intravascular hemolysis was associated with liver disease. This, the author states, he has recently confirmed clinically in cases of cirrhosis of the liver and splenomegaly associated with hemolytic anemia and hemoglobinuria.

Tuberculous Cervical Lymphadenitis: Epidemiology and Pathogenesis. B. C. Thompson.—p. 504.
Id.: Pathology and Treatment. E. S. Evans.—p. 510.

Sedimentation Rate, Leukocyte Count and Temperature in Pneumonia.—Douglas-Wilson determined the relation between the sedimentation rate, leukocyte count and temperature in forty-four cases of acute lobar pneumonia, in which there were ten deaths. Estimations were made daily throughout the febrile period and at regular intervals thereafter until recovery was complete. The mean sedimentation rate increased from the second (40) to the fourth day (81.38) of illness and then fluctuated around a constant level for the following three days with the maximal figure on the sixth day (82.91), before declining. In the case of the leukocyte count the mean figure fell from the first (187.1) to the sixth day (111.8), whereafter it rose till the ninth day (161.3). A slow decline ensued. Wide fluctuations above and below the average were found both in the sedimentation rate and in the leukocyte count. Body temperature had no influence on the sedimentation rate and leukocyte count. The only statistically significant correlation between the sedimentation rate and the leukocyte count occurred in the first four days of illness, but the trend of the signs of the coefficients suggests that, whereas at first they tend to be inversely related, the tendency in the later days is toward a direct relationship. This was confirmed by calculation of the correlation coefficient for each day by Sheppard's method. The change from inverse to direct variation occurred about the sixth day. In individual cases inverse variation was observed for a period varying with the duration of fever and occasionally persisted up to the tenth day of illness. The maximal, minimal and mean of the sedimentation rate in the fatal cases did not differ greatly from that in the cases in which survival occurred. A fatal outcome

invariably resulted with leukopenia but leukopenia was found in only a half of the fatal cases. In the other half a moderate and even increasing leukocytosis was found. In every fatal case the sedimentation rate began to decrease either two or three days before death, and this decrease continued up to the time of death. This progressive fall of the sedimentation rate, especially when accompanied by a high or rising pulse rate, has been found an excellent guide to the prognosis, resulting on several occasions in the accurate forecast of a fatal outcome which would have been otherwise unforeseen. In bronchopneumonia the same tendency as in lobar pneumonia toward inverse relationship of the sedimentation rate and leukocyte count in the febrile stage has been observed. The sedimentation rate remains increased longer during resolution in bronchopneumonia than in lobar pneumonia. As in lobar pneumonia, the sedimentation rate returned to normal only when resolution was complete.

Hematuria, Colic and Calculi After Sulfapyridine Therapy.—Snapper and his associates report the occurrence of hematuria during sulfapyridine treatment both in children and in adults. Of the three adults, the first had asymptomatic hematuria, the second hematuria and colicky pain, and the third hematuria associated with a renal calculus composed of acetylsulfapyridine. Several cases of hematuria in children have been encountered by the authors. They report one in which hematuria developed after thirty-six hours of medication. They believe that the recovery of a sulfapyridine calculus from the urinary tract in man has not as yet been recorded. According to recent experiments on rats, rabbits and monkeys, after continuous therapy with sulfapyridine the urine often shows small concretions consisting of needle-like crystals. These crystals prove to be acetylsulfapyridine. The same process appears to occur in patients treated with the drug. The highly insoluble acetylsulfapyridine which is formed during the metabolism of the drug precipitates in the urinary tracts, giving rise to crops of crystals and eventually to little calculi. Irritation or traumatism by the calculi would result in hematuria with or without renal colic. It is evident that in some cases, as observed by Southworth and Cooke, obstruction of the ureter by these concretions may lead to temporary anuria and nitrogen retention in the blood. Different animal species vary in their susceptibility to urolithiasis as a result of sulfapyridine administration. Whereas monkeys needed 0.25 Gm., rabbits from 10 to 15 Gm. and rats 5 Gm. per kilogram of weight daily for ten days, acetylsulfapyridine calculi developed in one of the patients after he received approximately 0.1 Gm. of sulfapyridine per kilogram daily for nine days.

Serum Treatment of Typhoid.—Yu treated sixty-four cases of typhoid with serum prepared with alcohol killed and live antigens. In thirty-three cases there was an immediate drop in temperature and a decrease in toxic symptoms. In nineteen there was a reduction in toxemia but no noticeable effect on the temperature curve. There was no change in the remaining twelve patients. The study substantiates the previous reports from the Lester Institute and the reports of Felix and other workers that the new antityphoid serum is definitely beneficial. The beneficial effect of this batch of serum on toxemia was more striking and constant than the effect on pyrexia. To date, a total of 305 cases of typhoid have been treated with this new serum. Although the number is still small, the good results obtained in the hands of the various workers justifies its routine employment in typhoid, more especially if toxemic features are in evidence.

- *Primary and Secondary Hypotension and Metabolism of Carbohydrates. H. G. D. Fisel.—p. 710.
- *Lipothymia in Chronic and Latent Appendicitis. A. C. Borcesco and V. Ionescu-Movila.—p. 750.

Hypotension and Carbohydrate Metabolism.—Fisel says that it was Ferrarini who first directed attention to a morbid entity which he designated as constitutional angiohypotonia and which is characterized by arterial hypotension resulting from deficient tonus in the vascular system and in other tissues. Fisel says that this form of hypotension is characterized by a more or less pronounced physical and psychic fatigue. Slight exertions exhaust these patients. Moreover, they have frequent painful sensations in the cardiac region such as retrosternal constriction, palpitations, sensations of emptiness, feelings of anxiety, and pains radiating toward the left arm. Hypoglycemic crises are known to occur in these cases. The sensations of hunger are suppressed by a small amount of nourishment, especially carbohydrates. Postprandial somnolence is a frequent symptom in these cases and general malaise, vertigo, headaches, dimness of vision, fainting, abnormal sensitiveness to cold on the part of the extremities, acrocyanosis, paresthesias, constipation and painful menstruation are other symptoms often observed. Since the clinical symptoms of hypotonia resemble those of hypoglycemic shock, Fisel decided to investigate the carbohydrate metabolism of patients with hypotonia by means of sugar tolerance tests. His studies were made on patients with primary hypotonia and on some with secondary hypotonia, forty in all. He designates as secondary that form of hypotonia which is encountered in the course of or after grave diseases such as acute infectious diseases, intoxications and cardiovascular diseases. After describing the characteristics of the blood sugar curves which he obtained in the two forms of hypotonia, he says that the clinical aspects and the studies on the carbohydrate metabolism lead him to conclude that primary hypotonia is the manifestation of an absolute displacement of the neurohormonal factors; that is to say, there exists an augmentation of the tonus of the vagal system and hyperfunctioning of the endocrine glands belonging to the insulin group. Secondary hypotonia is the manifestation of a relative displacement of the hormonal factors, that is, of hypotonicity of the sympathetic nervous system and of hypofunction of the endocrine glands of the adrenal group, or it is the expression of hepatic disturbances or of both hepatic and endocrine perturbations.

Lipothymia in Chronic and Latent Appendicitis.—Borcesco and Ionescu-Movila think that many cases of chronic appendicitis are not recognized because either they do not present symptoms permitting a definite diagnosis or the physician does not think of this disorder. In the course of a long practice, a careful search for symptoms indicative of chronic or latent appendicitis revealed to the authors three which they consider of great value. These are (1) appendicular vertigo, (2) lipothymia (faintness) and (3) urgent diarrheal stools preceded by colics which cease after evacuation. These three symptoms when associated in one case constitute a veritable symptomatic triad valuable for the diagnosis of chronic and especially of latent appendicitis. In this report the authors direct attention especially to the second of the triad of symptoms; namely, to lipothymia or faintness. After giving brief outlines of twenty typical examples of faintness in cases of appendicular lesions, they stress the following points: 1. Lipothymia is a symptom which is of great value for the diagnosis of chronic and latent appendicitis. Studies in 3,000 cases of appendicular lesions revealed it in 244, that is, in 8 per cent. 2. Lipothymia is sometimes associated with vertigo and with urgent diarrheal stools that are preceded by colics which disappear after evacuation. 3. Lipothymia can be considered as a symptom coming on unexpectedly with recurrences of chronic appendicitis, often announcing an appendicular crisis or as the first symptom of the onset of appendicitis. 4. It is important that the physician know the appendicular origin of lipothymia, so that in a case which, apart from other digestive disturbances, presents lipothymia, the possibility of a chronic appendicitis will be taken into consideration.

Pneumococcal Meningitis Cured by Sulfanilamide. E. Evrard and A. Bragard.—p. 622.

Therapy of Schizophrenia.—Discussing the various types of shock therapy of schizophrenia, Hoven says that insulin exerts a favorable effect especially on the paranoid, hallucinatory type of dementia praecox and on catatonic dementia praecox with agitation, whereas metrazol is most effective in stuporous dementia praecox and in late schizophrenia. However, treatment with metrazol presents certain inconveniences. It frightens some patients because it causes anguish and the feeling that death is imminent and so the patients refuse to submit to injection. Attempts have therefore been made to substitute other preparations which do not have the shortcomings of metrazol. In this paper the author discusses the use of azoman, which is known also as triazol and the chemical composition of which greatly resembles that of metrazol. After citing other investigators who have employed this substance, the author says that so far he has used it in twenty-five cases of schizophrenia and that he can confirm the favorable results obtained by others. He says that the substance is available in a 5 per cent aqueous solution and that it can be administered by intravenous or intramuscular injection. In general remarks about the dosage he cites studies by von Braunmühl in which it was determined that for intramuscular injection the dose should be 0.039 cc. of the 5 per cent aqueous solution per kilogram of body weight for men and 0.037 cc. for women; for the intravenous injection the corresponding doses are 0.023 and 0.021 cc. respectively. If a patient is in a hypoglycemic (postinsulin) state the doses are slightly different. The computation of the dose to be injected is not as complicated as it might appear; for instance, to a patient weighing 56 Kg., 1.2 cc. of the solution was administered by intravenous injection and to a patient weighing 59 Kg., 2.2 cc. was given by intramuscular injection. The authors report several cases in which they employed the substitute of metrazol. They reach the conclusion that, if utilized with caution, the new preparation has great advantages and produces good results in schizophrenia.

- *Therapeutic Value of Autonomous Pleurotomy. F. Dumarest and P. Pavie.—p. 1285.
Hematoporphyrin Therapy in Pyramidal Hypertonia. W. Sterling and W. Stein.—p. 1287.

Pleurotomy in Artificial Pneumothorax.—Dumarest and Pavie evaluate the advantages of pleurotomy in pleural complications of artificial pneumothorax. In their analysis of the threefold objection to this surgical procedure, namely the dangers of secondary infections, the risks to the organism of prolonged suppuration and the irremediability of thoracic fistulas when once established, they present the following considerations: 1. Pleural infections occur almost entirely in exceptional cases, such as when surgical intervention is performed on cachectic patients as a last desperate measure or when poor drainage causes retention of infective matter. A correctly performed and maintained drainage eliminates, in principle and practice, all infectious evolution. 2. Clinical observations show that pleurotomy is no hindrance to a gradual establishment of excellent well being with a rapid gain in weight and that it does not lead to amylosis. The inconveniences of prolonged suppuration diminish in time. 3. The spontaneous occlusion of fistulas is of frequent occurrence when drainage has not exceeded several months. In thirty-nine recent pleurotomies the authors, jointly with Rougy, their deceased collaborator, could report closing of parietal fistula in eight cases, five with symphysis and three with conservation of the pneumothorax. In their discussion of the advantages of pleurotomy, the authors point out that its pulmonary significance apart from any pleural value lies in the fact that rarely homolateral or contralateral pulmonary evolutions are found in cases in which an effective pleurotomy has been performed. According to the authors, pleurotomy offers the following pulmonary advantages: (1) It protects the oppo-

site lung from infection in the event of perforated pneumothorax and has surprising curative effects on existing contralateral lesions; (2) it completes the collapse of the lung under treatment; (3) it facilitates the occlusion and cicatrization of pleuropulmonary fistulas in intermittent and latent cases in which surgery is performed without delay. Wide, open fistulas, however, persist but are easily endured by the patient if drainage is properly continued. The clinical experiences of the authors, therefore, do not confirm alleged dangers to the pleura and lungs. On the contrary, surgical delay and prolonged pleural lavage may convert an intermittent into a permanent fistula and induce fatal consequences of pulmonary inundation. Nor are tuberculous pleurisies of malignant evolution benefited by puncture and lavage, rapidly becoming cachectic. Open pleural cavities in cases of complete pneumothorax in which infection is maintained by a permanent pleuropulmonary fistula can be stabilized effectively for a long time by pleurotomy. The advantage of pleurotomy over thoracoplasty in pleural infection rests on avoiding the necessity of an early severe operation with its high fatality when the patient is in a precarious condition and in restoring him progressively to the resumption of at least a partial customary activity of life. The inconveniences of permanent drainage receive their proper evaluation in the scale of relative human values in the sentiment expressed by one of the author's patients that it is better to live in ill health than to die while being cured.

*Mammography: X-Ray Examination of Milk Ducts by Using Contrast Mediums. A. E. Nogués and C. L. Gazzotti.—p. 999.

X-Ray Examination of Milk Ducts.—Nogués and Gazzotti made an x-ray study of the milk ducts (so-called mammography) of a group of nine women. They resorted to Hicken's technic, which was reported in *Surgery, Gynecology and Obstetrics* in March 1937 and abstracted in *THE JOURNAL* May 1, 1937, page 1575. The procedure utilizes a contrast substance, which is injected into the milk ducts for x-ray study. The authors used a 30 per cent solution of thorium dioxide sol. They describe in detail and also by illustrations the x-ray aspects of the milk ducts in normal conditions, during lactation and in the presence of mammary or intracanalicular tumors, as well as in the presence of the bloody, white and yellow discharge from the nipple. The authors found that the procedure is harmless if it is carried on by the proper technic. The method has proper indications, namely (1) the diagnosis of intracanalicular tumors or of inflammation of the milk ducts, (2) diagnosis of the intracanalicular tumoral (or nontumoral) origin of the bleeding nipple and (3) the differential diagnosis of various types of white and yellow discharge from the nipple. The authors found that milk ducts which harbor a tumor (papilloma or carcinoma) give mammograms with shadows showing ampullar dilatation and a lacunar image. The nature, either benign or malignant, of the tumor cannot be diagnosed from the aspect of the mammogram. Clinically intracanalicular papilloma shows by the bleeding nipple. Therefore the x-ray appearance of the bleeding nipple from intracanalicular papilloma is that of milk ducts harboring a tumor. Mammograms of breasts with a white or yellow discharge which is due to any of the various types of acute and chronic inflammation of one or several milk ducts, with or without complicating canalicular abscess, are those which correspond to the given type of inflammation and to the evolution of the conditions. The x-ray aspects in the conditions are varied. Generally the mammograms give shadows showing more or less intense ampullar dilatation of the involved ducts or else pseudocavities, retraction and anfractuosités. The mammograms can be differentiated from those of breasts with secretion from the nipple which is due to mammary tumors without involvement of the canalicular system, which shows normal at the mammogram. In the diagnosis of paraductal tumors without involvement of the ductal system, mammography has a secondary value. The seat, form and number of the tumors can be interpreted from the deformation of the ducts from the neighboring tumors. Cancer of the breast can be suspected by

a mammogram which shows deformation of the milk ducts and destruction of the ductal branches as they touch the tumor, which is shown by a dark shadow which absorbs the ductal branches as though the latter were amputated by the former.

Free Gases in Rapid Decompression.—Schubert and Gruner studied the question of the development of gases in blood and tissues during sudden transition from extremely low to normal atmospheric pressures and aimed to determine whether the danger of gas embolism can be averted by prompt return to normal pressure. A solution of these questions seemed important in connection with flying in the stratosphere. Experiments on rats which were subjected to low atmospheric pressures (70 mm. of mercury) and then were returned to normal pressure gave information about the pathogenesis of atelectasis. The development of gases and gas embolism were likewise investigated on rats as well as on other species of animals (guinea pigs, cats and dogs). The authors show that their experiments give information about the dangers threatening persons who fly at stratospheric altitudes, when the chamber or the pressure suits suddenly become defective. They found that even a brief transition (less than one minute) to pressures between 75 and 70 mm. of mercury, that is, to altitudes of from 16,000 to 17,000 meters, is not necessarily fatal if a return to greater pressures is effected immediately. However, the longer the aviators stay at this pressure, the more extensive are the tears in the pulmonary tissues and the hemorrhages into the alveoli and bronchioles. These represent the life threatening factor, even if the return to normal pressure lasts only seconds, whereas the development of gases represents an entirely reversible process. A stay of more than ninety seconds in pressures of less than 60 mm. of mercury is absolutely fatal, for a return to normal pressure, even for seconds, produces not only a complete atelectasis of the lung but also the development of such quantities of gases that the circulation in the vital organs is at once impaired and remains so permanently. The authors show that there are physiologic and technical protective measures against these dangers. The most effective physiologic one is that as soon as the chamber or the pressure suit become defective a voluntary hyperventilation is begun in order to effect equilibration of pressure between lung and external air and thus avoid tearing of the pulmonary parenchyma and also to reduce the tension differences of gases by increased diffusion. The technical protective measure consists in provision with tanks containing highly compressed oxygen. They should be discharged under high pressure to be regulated automatically by the pressure of the chamber. The same automatic regulation should be provided during steep descent.

Pathogenesis of Renal Hemorrhages During Diphtheria.—Stiepel points out that hematuria is occasionally observed in cases of diphtheria. Reviewing different opinions about the source of these hemorrhages, he says that Randerath demonstrated in 1933 that renal hemorrhages in diphtheria represent glomerular hemorrhages brought about by capillary

impairment and that the appearance of erythrocytes in the urine of diphtheria patients does not permit the conclusion that a glomerular nephritis exists. On the basis of his microscopic studies, Randerath could exclude not only glomerular nephritis but also glomerular irritation and glomerular hemorrhages as the result of stasis, and he interpreted the hemorrhages as the manifestations of impairment of the glomerular capillary walls. He thinks that these hemorrhages can be regarded as equivalent to the cutaneous and to the subserous and subendocardial hemorrhages of diphtheria patients. Since Randerath's conclusions were based on a single observation, Stiepel decided to reexamine his results in a larger number of cases. He made microscopic studies on the kidneys in fifteen fatal cases of diphtheria and, in addition to purely nephrotic changes in the region of the tubules, he observed in eight cases in circumscribed regions of the renal cortex massive hemorrhages into the glomerular capsules and into the lumens of the uriniferous tubules. The author agrees with Randerath that these hemorrhages originate in the glomerular coils and that they are the result of an impairment of the walls of these coils, which in turn is a manifestation of the generalized capillary impairment during diphtheria. The microscopic aspect of all eight cases demonstrate clearly that the presence of erythrocytes in the urine does not permit the conclusion that inflammatory processes exist in the kidney. Their appearance in the urine is only an indication of the severity of the existing capillary changes.

Venous Pressure in Pneumonia of Children. L. B. Krasik.—p. 315.

Hepatopulmonary Syndrome in Lobar Pneumonia.—Vilkovskiy sensitized rabbits by intravenous injection of horse serum or of a dead culture of pneumococci or streptococci, after which the horse serum was administered either by inhalation or by the intratracheal route, or by the combination of the latter with simultaneous injection of pneumococci into the blood stream. The effect of cooling, analogous to "catching a cold," was likewise estimated. These experiments, carried out on eighty animals, demonstrated the role of the allergic factor in the genesis of lobar pneumonia, the possibility of producing sensitization by various agents, such as heterogeneous proteins, nonspecific or specific micro-organisms, the possibility of producing pneumonia through hematogenous introduction of the infectious agent, the relatively greater importance of the pneumococcus as the determining factor, and the role of cooling, which increases the hyperergic reactions but is of little influence outside the conditions of sensitization. The author points out an analogy between some of the metabolic functions of the liver and the lungs, such as the removal of excess lactic acid, and the nitrogenous and the chloride metabolism. In order to study the carbohydrate metabolism in experimental pneumonia, the author first determined the glycogen content of the liver, the muscles and the lungs of five control rabbits. A similar study was made of fifteen rabbits in which experimental pneumonia was induced by sensitization with intravenous injection of horse serum, followed by intravenous injection of a culture of pneumococcus, and by intratracheal introduction of horse serum. There was noted a lowering of the glycogen content of the liver to almost one tenth of the normal, while the muscle glycogen content showed slight increase, whereas the glycogen of the altered pulmonary tissue exceeded that of the control animals by 167 per cent. These experiments demonstrated marked alteration of liver function at the height of the hyperergic inflammation of the lungs. Tissue metabolism of the liver, of the unaffected lung and of the affected lung of nineteen rabbits was studied. There was noted a marked lowering of tissue respiration in the liver and a slight increase in glycolysis. In the pathologically altered lung there was a fall in tissue respiration and an increase in glycolysis. A diminution of respiration was likewise noted in the normal lung, a fact having a bearing on the anoxemia of pneumonia patients. Of the pneumonia patients

observed by the author, 22 per cent had an enlarged and tender liver. Many of these had urobilinuria. On the theory that the detoxication function of the liver depends on its glycogen content, the author applied insulin-dextrose therapy, first suggested by Kogan-Yasnny in cases of lobar pneumonia. In a group of seventy-four patients with pneumonia treated by the insulin dextrose therapy, the mortality rate amounted to 5.4 per cent, while in a group of 131 patients treated during the same period on an orthodox regimen, the mortality amounted to 15.2 per cent. The author believes that the beneficial influence of the insulin-dextrose therapy is due to the improvement in the glycogen synthesis with the resulting increase in glycogen storage in the liver, which in turn increases the antitoxic function of the liver. The increased glycogen content also may exert a favorable effect on the allergic reactions.

Progestin in Repeated Abortion.—Tholen and Stolte first review the present status of the knowledge about progesterone, the hormone of the corpus luteum, giving especial attention to its role in the preservation of pregnancy. They cite factors which indicate that a deficiency of corpus luteum hormone plays a part in habitual abortions and that the injection of this substance is a valuable aid in counteracting habitual abortion. Further they review the clinical histories of nine women in whom pregnancy usually terminated in abortion, twenty-nine pregnancies producing only two living children. After treatment of these women with progesterone was instituted, twelve pregnancies resulted in eight living births; to be sure, the authors admit that these probably cannot all be ascribed to the action of progesterone. Nevertheless, they are convinced that progesterone represents a valuable addition to the therapeutic armamentarium of habitual abortion. They think that larger doses than were employed by them might perhaps produce better results. The small doses employed at present and the defective differential diagnosis still necessitate a combination with other therapeutics such as a salt-free diet, thyroid and vitamin E.

Pneumococcic Peritonitis in Children.—Haglind says that genuine or cryptogenic pneumococcic peritonitis, in which the peritoneal fluid contains only pneumococci and in which neither operation nor necropsy discloses a local point of origin, has received considerable attention in different countries and so he decided to review the cases that were treated in Swedish hospitals during recent years. All of the seventy-seven patients who were the subject of his review were children less than 16 years of age. In all of the cases the diagnosis was bacteriologically verified. The majority of the patients (92 per cent) were girls and most of them were between 6 and 10 years old. The pneumococcic peritonitis seems to be a primary process in the majority of cases, for in only a small number did it appear as a secondary phenomenon to other forms of pneumococcic disorders. As regards the symptomatology, it is of especial interest that the anamnesis frequently reveals diarrheas, that the fever is high from the beginning and that the general condition is poor from the onset. The mortality of pneumococcic peritonitis is high, in the material reviewed here 66 per cent. The differential diagnosis is difficult and efforts have been made to find methods which will permit a definite diagnosis before an operation is resorted to, because a surgical operation during the acute stage of this form of peritonitis seems to increase the risk of death rather than reduce it. The author shows that explora-

tory puncture has been recommended by some as a diagnostic aid. In remarks about the pathogenesis he cites the various possible routes by which pneumococci might invade the peritoneum. In view of the fact that the majority of patients are girls, he considers a genital mode of infection possible; on the other hand, he shows that there is considerable evidence for an enterogenic infection. He says that in the treatment of pneumococcic peritonitis a conservative tendency has been gaining during recent years, although the debate about surgical or conservative treatment is still not definitely decided. The fact that pneumococcus type I seems to be the cause of the peritonitis in more than two thirds of the cases is of great interest for a possible serotherapy. The author further suggests that in view of the favorable results obtained with sulfapyridine in pneumonia it might be advisable to try this preparation also in pneumococcic peritonitis.

Pericardectomy in Fibrous Pericarditis.—After reviewing the literature on surgically treated cases of fibrous pericarditis and following remarks about the pathogenesis and diagnosis, Köster reports two cases in which the classic symptoms of fibrous pericarditis were present: increased venous pressure with protruding veins, coughing, ascites, enlarged liver, edemas, reduced beat volume with lowered blood pressure, small pulse, cyanosis, oliguria, exertion dyspnea, tachycardia and fatigue. Before, during and after pericardectomy the oscillations of the pulse volume were registered by means of Liljestrand-Zander's method, in which 0.7 mg. of epinephrine is injected previous to the registration of the pulse and the beat volume. This method yielded results similar to those obtained by other investigators with Grollmann's method. In the surgical treatment of the two patients, pericardectomy was preferred to Brauer's operation in spite of the fact that many regard the latter as adequate and less dangerous. In the first case, although the symptoms had existed a long time, the fibrous pericardium could be detached fairly readily and extensively and the patient's condition was much improved after the intervention; she is able to work. In the other case the condition developed rapidly after an attack of acute pericarditis; technically the operation was extremely difficult and only a small portion of the pericardium was resected. However, in spite of the less radical intervention, this patient made a more rapid and better recovery than did the first one. Following remarks about the problem of drainage in pericardectomy, the author says that after the operation the patients were treated with digitalis and morphine. He thinks that the postoperative prognosis seems to depend not so much on the size of the resected piece of pericardium as on what damage the heart has sustained under the influence of inactivity and compression and to what extent the disorder which caused the pericarditis (usually tuberculosis or rheumatic infection) has subsided. Operation during the acute stage is technically easier, but it involves greater dangers for the patient, and for this reason some authors advise against pericardectomy during the acute stage.

Magnesium Content of Red Cells in Anemias.—Bang and Ørskov state that an increased magnesium content of the erythrocytes seems frequently to follow in anemias originated because of relatively acute loss of blood and is further demonstrated in some anemias of long standing. In anemias due to hemorrhage as well as in experimental animals (Ørskov and Henriques) an increased magnesium content is believed to be a phenomenon connected with newly formed red blood corpuscles. In the majority of cases of pernicious anemia high magnesium values are present in the untreated stage and the relations approach normal values during remission. The view is thus supported that a short lifetime of red cells with concomitant increased rate of destruction is a decisive factor in the development of pernicious anemia.

AFTER-EFFECTS OF HEAD INJURY

THE POST-TRAUMATIC CONCUSSION STATE (CONCUSSION, TRAUMATIC ENCEPHALOPATHY) AND THE POST-TRAUMATIC PSYCHONEUROTIC STATE (PSYCHONEUROSIS, HYSTERIA): A STUDY IN DIFFERENTIAL DIAGNOSIS

WALTER F. SCHALLER, M.D.
SAN FRANCISCO

Head injuries from warfare and from industrial and automobile accidents have in recent years occasioned a constantly increasing number of claims for awards, based on veterans' and industrial compensation laws and on public liability. The economic importance of a proper understanding of the physical and mental results of such injuries, from the standpoint of both occupational disability and future outlook for recovery, therefore is of great importance. Head injuries may be classified as organic or functional, dependent on the presence or absence of structural changes in nervous tissue. In the first category, that of organic injuries, are placed brain pressure by depressed skull fracture, epidural or subdural hemorrhage, lacerations, contusions, softening and complicating infections such as meningitis or abscess. The symptoms and signs of these more evident injuries have been carefully studied and classified as to demonstrated pathologic features, the treatment has been standardized and the prognosis has been fairly well evaluated, so they will not be dealt with in this paper. In the second category, that of functional disorders, are placed the post-traumatic psychoneuroses or traumatic hysterias, purely psychogenic states which develop out of mental complexes following the acute symptoms. Traumatic psychosis will not be considered here. Midway between these two contrasting pictures is the post-traumatic concussion state, an after-effect of injury variously designated as traumatic encephalopathy, traumatic encephalitis, cerebral neurasthenia, post-traumatic head syndrome, traumatic constitution, punch drunk, or concussion neurosis. I shall hereafter use the term post-traumatic concussion state, or simply concussion, to designate this group. I propose to define the term and describe the condition, particularly in differential diagnosis from the functional state. The term concussion, therefore, is employed to distinguish it from brain bruising or contusion; in an uncomplicated picture it indicates no gross primary brain injury. It is caused by a different traumatic mechanism than contusion and produces a temporary abeyance of brain

function; severe concussion, however, may result in irreversible brain changes. Only the later effects of brain injury are here considered, namely, those of patients who have recovered from all acute symptoms and have entered on a more or less chronic course.

THE POST-TRAUMATIC CONCUSSION STATE (CONCUSSION, TRAUMATIC ENCEPHALOPATHY)

Characteristic of brain concussion is a disturbance of consciousness, with no immediate or obvious pathologic change in the brain. It may or may not be followed by brain edema and increased intracranial pressure, depending on the severity of the injury. The early definition of Koch and Filehne¹ well describes the clinical picture.

Concussion is a state of more or less disturbed consciousness with lost or practically lost reflexivity. The appearance is that of sleep or apparent death, there is occasional vomiting. The respiration is slow, shallow and regular, the pulse is weak, slow and generally regular, the pupils are dilated and react sluggishly, the temperature is subnormal.

Physicians do not know the neural mechanisms which produce unconsciousness or, indeed, the anatomic seat of consciousness. Concussion is a reversible and recoverable phenomena in the great majority of cases; however, in severe concussion states, both of the human being and of the experimental animal, definite pathologic changes have long been recognized and described as affecting the myelin (Schmaus² in experiments on spinal cords), the ganglion cells (Jakob³) and the blood vessels (Kocher⁴). In the past, much experimental research has been done on the nature of concussion; this was thoroughly reviewed up to the past few decades by Kocher.⁵ A few of the most important of the experiments may be briefly mentioned: Duret⁶ produced concussion in dogs by the sudden and forceful injection of fluid into the cranial cavity, and Koch and Filehne¹ by hammering on a board applied to the cranium. The latter authors studied the effects on brain centers and concluded that the intracerebral effects were general; all centers—respiratory, vasomotor, vagus, and pupillary—were affected and in the end became exhausted, so that function was impaired.

Ferrari⁷ ingeniously placed capillary tubes filled with colored fluid and cover glasses in various parts of the brain; after concussion there was no breakage less than 5 mm. from the surface. It was observed that concussion effects were most marked in areas of transition between gray and white matter, substances of different densities. Apparently the transmitted force underwent a change of rhythm or pace, producing disruption of normal anatomic structure or disturbance of physiologic function. Kocher cited a celebrated case of cerebral softening,⁸ reported by Hauser, which principally affected the white substance, was not due to vascular occlusion and caused death six days after injury. He held that the main effect was in the direction of the line of impact and that the vibratory method of experimental concussion, "hammering," was not reasonably comparable to the impact blow ordinarily producing concussion.

Scagliosi⁹ first suggested that traumatic myelinic necrosis without infarction was due to damage of the neuroglia, an idea based on Cajal's theory of the nutritive function of this tissue; in support of this idea, Rand and Courville¹⁰ found swollen oligodendroglia cells in injured brains, cells which are in especial maintenance relationship to the nerve fiber. More recent investigations have dealt with cerebral vascular changes such as are produced by the vasovagal reflex, namely, alterations in arteriolar, capillary and venous pressure and in the size of vessels and the resulting changes in blood flow and osmotic relationships. In this manner stasis, edema and anoxemia are produced.

Bright and Rokitsky, according to Gussenbauer,¹¹ first called attention to the presence of "punctiform" hemorrhages in concussion. It was Ricker¹² who first suggested that these small hemorrhages were produced by diapedesis and not by rhexis. He concluded that neurovasomotor disturbances produced vessel dilatation, stasis and consequent anoxemia. Cobb¹³ stated that he did not unconditionally accept Ricker's vasomotor theory of diapedesis because of the relatively feeble nerve supply to the brain vessels. Interest in blood vessel pathology has recently been revived by Cassasa's¹⁴ theory of capillary rupture by rhexis due to tearing of the vessel wall by hydrostatic pressure suddenly transmitted from the subarachnoid space to the perivascular space. Osnato and Gilberti¹⁵ and Martland and Beling¹⁶ have described clinical syndromes of traumatic encephalitis and "punch drunk."

With Dr. Tamaki and Dr. Newman¹⁷ I examined a series of brains of human subjects who had died of head injuries. Serial sections were made of a number of areas showing punctiform or petechial hemorrhages. The petechiae were perivascular and fairly constantly

found in these brains, but they varied in size. They rarely affected the cortex but were found in the subjacent white matter and in the deeper collections of gray matter and in the brain stem. Almost invariably were the hemorrhages the result of diapedesis, observations thus not confirming Cassasa's theory of rupture. Our study was extended to concussion experiments on white rats, the controls being normal, untraumatized animals. By securing the animal on the end of a lever, which would be released at different heights, a traumatic head injury was produced similar to that effected by propulsion impact, a mechanism common in automobile injuries and falls. Petechiae similar to those demonstrated in traumatized human brains were reproduced. A report on these results is as yet unpublished. The traumatized brains were studied at different intervals after trauma. For the most part there were no marked departures from the normal, but in severe brains perivascular gliosis was marked about a few vessels, as has been described and pictured by Rand and Courville.¹⁸ Other vessels were obliterated and replaced by glia, and rarely vessels, obviously damaged, showed aneurysm-like degeneration and irregularities of their walls with fresh perivascular extravasations. We have therefore demonstrated in animals that in certain cases of brain concussion vessel damage is produced which runs a definite course with tendency to reparation but which may cause late accidents by vessel rupture, producing late apoplexies and softenings. As yet, however, we have not demonstrated such a late vascular accident in a series of thirty-five animals. This demonstration of structural brain effects following concussion justifies the designation of "encephalopathy." Functional impairment from vasomotor irregularities may be assumed, but as yet only assumed, to justify the term concussion neurosis.

The course of a moderately severe case of brain concussion is one of quick recovery from the immediate symptoms of shock. The duration of residual symptoms in severe uncomplicated cases rarely exceeds three months and is often considerably shorter. Symptoms of the postconcussional state are headache, vertigo, tinnitus, nervousness (usually described as explosiveness and irritability), impairment of memory (which may include events immediately preceding the accident), impairment of vision, fatigability, poor concentration, sensitiveness to heat and intolerance to alcohol. Examination often reveals a hopeful rather than discouraged patient, with a normal pulse but not infrequently a low blood pressure and a far lower incidence of lively reflexes, vasomotor disturbances and tremors than to be found in the psychoneurotic group.

Severe cases of concussion may be complicated by laceration and contusion. Even moderately severe cases of concussion may be accompanied by small surface hemorrhages of the pia arachnoid, by far the most common of all traumatic lesions. As a rule, contused and lacerated wounds of the brain may be regarded as subject to the same conditions of repair as elsewhere in the body. In the severest cases of brain injury, complicated by contusion, it is probable that the general symptoms and disability, excluding epilepsy and loss of specific function from focal lesions, are due to permanent concussion effects. The postconcussion picture differs from that following a gross lesion, as apoplexy or lobotomy for removal of a brain tumor, as any exper-

rienced neurologist can testify. I am not prepared at the present time to define precisely the mechanism or pathology of severe concussion, but sufficient evidence is at hand for one to recognize both the pathologic picture and the clinical course, as distinguished from those of laceration and contusion, on the one hand, and the psychic counterpart, on the other.

THE POST-TRAUMATIC PSYCHONEUROTIC STATE (PSYCHONEUROSIS, HYSTERIA)

The psychoneurotic states following trauma have been variously designated as traumatic neurosis, traumatic hysteria, litigation neurosis and compensation hysteria. I have favored the term post-traumatic psychoneurosis as one which particularly describes this condition, as it includes whatever psychic manifestations of the disorder may be present in the individual case, whether they are of neurasthenic, psychasthenic, hypochondriacal or hysterical nature; it also places the onset not at the time of trauma but after it. By definition a psychoneurosis is a condition of the mind whereby unfavorable mental influences disturb the function of the body through nervous mechanisms. According to Smith,¹⁹ writing on neurosis in students, a psychoneurosis always serves the patient a useful purpose. Schwab²⁰ discerned in the war neuroses and incipient neuroses a defense mechanism. To escape from disagreeable situations there is a subconscious flight or escape into invalidism and conversion of normal bodily functions into abnormal ones. This is typified by the hysterical picture of loss of function but may be expressed by positive symptoms such as pain, uncontrolled motor behavior, anxiety and compulsions. I am aware that this extends the idea of hysteria beyond the usual symptomatic picture. The theory of conversion hysteria, however, should be valid not solely for a conventional pattern of response but also for such patterns as individual suggestibility and concepts dictate.

It appears to me that classifications of the neurotic state based on symptomatology have become unwieldy, and this holds also for the complexities of mental mechanisms sought to explain them. There is need for simplification and more basic concepts. It also appears to me that the compensation neuroses offer a particularly favorable opportunity to study basic motivations and fundamental life situations without the complications of fatigue and changed environment, as found in the war neuroses. A psychoneurosis may be likened somewhat to somatic disease having a comparatively simple etiology but an exceedingly complex symptomatology.

The term psychoneurosis will be used as the inclusive term and hysteria for the usual picture. Oppenheim²¹ unfortunately designated the symptom complex now under consideration as traumatic neurosis, thus emphasizing the traumatic rather than the mental nature of the condition. His theory of a molecular change in the brain cells of course assumed something not in evidence. As one now reviews his writings, one is impressed with the admixture of symptoms now generally agreed on as psychic, such as functional anesthetics and concentric contractions of the visual fields, with symptoms due to concussion or even contusion. The Great War definitely settled the essentially psychic etiology of the

so-called traumatic neuroses. A comprehensive exposition of the subject of the accident neuroses has been contributed by Huddleson.²² Whatever theory one may apply to the cause of hysteria, the theory of suggestion, of freudianism or of conversion, there is general agreement (1) that the mechanism is purely mental, (2) that the condition is curable, (3) that this cure is brought about by mental readjustment and (4) that the cure is often brought about with such dramatic rapidity as to exclude any structural nerve change as playing any role whatever in its production.

Many years' experience leads me to believe that the ultimate psychogenic factors underlying true hysteria consist of the emotional and instinctive reactions of fear and suggestion and of wishful thinking. Serious character defects and adverse mental influences often complicate the picture. Hall and MacKay²³ discerned in the post-traumatic neuroses "marked neurosis or marked ineffectiveness of the personality before injury." Does a man refuse to work because he is covetous, indolent, antisocial, querulous or resentful, dramatizing and enjoying his invalidism; or is he of an essentially apprehensive, suggestible temperament, fearful that by returning to work and thereby forfeiting his compensation he will jeopardize his health by possible relapse of symptoms and his social security by inability to continue at occupation? Obviously, one should receive greater consideration than the other and be more amenable to rehabilitation. Persons with marked character defects are but too eager to capitalize on a minor injury; this desire is often furthered by the sympathy and solicitude of friends and relatives, by lack of occupation and interest and by an undesired compensation award, based on a complete misunderstanding of the case and misdirected treatment, which tend to fix the psychoneurosis. Following injury a period of meditation ensues wherein inadequate personality traits and adverse mental influences combine to create a psychic climax and a point of negative departure from the natural tendency to recovery. This point of negative departure of efficiency is the "precipitation point"²⁴ and averages three months and seventeen days after injury. It is interesting to note that this approximates the independent estimates of Fay²⁵ and Munro²⁶ of reasonable recovery from the ordinary head injury.

In conduct and appearance the post-traumatic psychoneurotic patient is nervous and somewhat tense and depressed, eager to establish his claim of disability and voluble in detail. His good order of thought and memory in regard to his accident and subsequent history are often in striking contrast to his assertion of poor memory and concentration and mental fatigue. He deals in superlatives, picturing in dramatic style the seriousness of his injury and acuteness of his suffering. He is apt to be emotional and querulous and often asserts that he is doubtful of betterment. His complaints are numerous and on recheck examination are frequently amplified and augmented. Headache and dizziness, especially the former, are almost constantly complained of.

The examination of the psychoneurotic person is often a trial to the physician because of the finching, groaning and gasping which interrupt the different tests. These patients often complain of an actual setback in their illness because of the ordeal of the examination, despite its being made with considerate care. Very often a tremor is present when the patient is asked to extend his fingers; this may diminish or cease on distraction. Sweating and lively reflexes are common. Perhaps the most prominent trait of the neurotic patient is his tendency to exaggerate in his response to tests. For example, he will show no disturbance of gait and yet will respond to tests of muscular force at the ankles by a weakness incompatible with normal walking. He will grip a dynamometer in a stiff-armed, effortless fashion. If he claims hemianesthesia, he will respond to sensory tests on both the affected and the non-affected side with a meditated negativism which betrays a lack of candid response. Often when the limbs are crossed the patient will make flagrant errors in his responses, giving a ridiculous answer in the yes-no test. It is therefore but little wonder that the general practitioner and surgeon not trained in the complexities of psychopathologic reactions consider these patients as malingerers. It is generally held that "tests" for malingering holding valid with reference to organic disease are invalid with reference to hysteria.²⁷ A distinguished psychiatrist, Aaron J. Rosanoff,²⁸ commented on this statement by expressing the opinion that this is a distinction without a difference.

I myself do not feel that every post-traumatic neurotic person of hysterical type is a malingerer, but I do believe it is consistent with the facts to say that he is at least a subconscious simulator. A conscious simulator is a malingerer (to simulate: Latin, *simulo*, *simulatus*, to assume the signs or appearance of, to imitate; to malingere: French, *malingrer*, to feign illness or disability). Malingering, therefore, is of greater moral implication than simulation and may in this regard be likened to the legal term of perjury. As a medical definition I should characterize malingering as conscious, intentional and deliberate deception practiced for profit or gain. Simulation is of milder implication as regards motives and conduct. A patient may show a complete sensory loss in an extremity but also show in ordinary use of this extremity complete physiologic function, namely, sensory orientation, proprioceptive function and subconscious protection from injury. In hysterical paresis unconscious function by conventional patterns is often observed. In this sense, every hysteria is a simulator; simulation and malingering may coexist. A hysteric, in order to impress the examiner, may consciously simulate. Certain tests have been devised in order to determine the good faith of the subject and a number of these are of doubtful value. For instance, a pin may be suddenly thrust into an allegedly anesthetic extremity and the patient brusquely withdraw this extremity. However, that this may be a purely reflex phenomenon is established by a similar reaction in a completely divided spinal cord. Pinching of the allegedly anesthetic skin of the neck may cause a dilatation of the pupil on the corresponding side. The pupil, however, may dilate as a sensory motor reflex without conscious perception.

It is my impression that there has been in late years an increasing tendency of courts and commissions to

be too lenient in dealing with neurotic persons. Two quotations are here relevant, one²⁹ from a lay journal, the other³⁰ from a medical journal, voicing the experience of physicians who served in the Veterans' Administration. Those who have followed cases through the courts and accident commissions have often been greatly surprised by favorable decisions for the applicant based solely on subjective symptoms. Further, an inconsequential injury is stressed which should be considered only as a point of meditative departure for the establishment of a neurosis, and no clear distinction is made between ability to work and lack of desire to work.

In many cases, therefore, a mildly traumatized neurotic patient is compensated for defects in character and temperament rather than for injury. For an alleged injury to be etiologically valid, it should be of such prominence and importance as to be an acceptably dominant causative factor. The traumas or residuals of trauma in the traumatic psychoneuroses are not proximal or dominant factors but are remote and secondary. That this view is not extreme is evidenced by the position of Claude,³¹ in France, who has urged that no compensation be awarded on account of traumatic neuroses of civilians, and in decisions of German courts³² denying compensation for hysteria following trauma.

The prognosis for recovery in the psychoneuroses depends on when and whether the patient's character and temperament, i. e., his personality, can strike a balance with the adverse psychic factors arising both from within and from without himself. In other words, is the patient so mentally constituted, controlled, and desirous for recovery and work that he can overcome adverse and uncomfortable situations and again take his place as a useful member of society and as a social asset rather than a social liability? The greatest help that a psychoneurotic patient receiving benefits can be accorded is final settlement of his claim and return to occupation. This is demonstrated by a follow-up investigation of cases reported by me³³ in 1918.

29. The Betrayal of Popular Government, editorial, Sat. Eve. Post, Nov. 26, 1938: "The weaknesses that now beset popular government, especially our own foremost example of it, are not those of disaffection. They are weaknesses of character, of faith, of conviction, and are manifest in self distrust, in the flight from individual responsibility, dread of pain and hardship, a morbid anxiety about the pulse and circulation, love of security, the habit of turning to the government in every dilemma, the shameless struggle of groups and classes for access to the public purse, and a kind of cynicism that says, 'Because those got theirs, now we shall have ours,' until at last we see a total failure of the stern, parent tradition in American government, and in place of it the idea of beneficent government, a power at Washington, omnipotent and wise, to absorb the people's troubles, to feed and clothe and house them, to divide the national income among them by a rule of wisdom, and increasingly to administer their lives."

30. Aring, C. D., and Bateman, J. F.: Nurturing a National Neurosis. J. A. M. A. 109:1092 (Oct. 2) 1937: "The family life of veterans suffering from psychoneurosis was inquired into both from the veteran and from the wife who occasionally accompanied them. These veterans as a rule report their families well and happy, but their wives tell a different story. It is not unusual for the wife when queried in private to note that a child is 'just like his father,' with many of the same somatic complaints, fears, food fads and addition to medicines, and express rather indirectly her own dissatisfaction. This seemed significant, although we have no statistical data on the subject. It would well form an excellent subject for investigation. It is a remarkable fact that the majority of these men assume the additional responsibility of a wife (repeated marriages seemed quite high in these veterans) and numerous children, despite the lack of energy and numerous complaints leading to invalidism or semi-invalidism. We hold no brief for the strict environmentalist, but children raised in the enervating atmosphere created by these individuals are certainly not bettered by it. Imitation of parents is a large and recognizable factor in the mental development of all of us. The onus for sponsoring a national neurosis therefore is not too large an indictment, when one considers what is taking place in our national life as a result of this unenlightened method of the treatment of a large group of the psychically ill."

This article does not concern itself with treatment, but it may not be amiss to assert that in the majority of cases of post-traumatic psychoneurosis, especially those of long standing, say over a year, there is no medical treatment or psychotherapy which offers any great chance of success. True, in some cases major hysteria based on fear and suggestion clears up under

intensive persuasive methods reinforced by a lump sum settlement, which also acts as a prophylactic against a relapse. I am of the opinion that more of these patients would recover, or their state perhaps not be established, if no compensation law existed. The treatment of a traumatic psychoneurosis is to recognize its onset at the precipitation point and to make it unpopular and unprofitable. In none of my cases of post-traumatic psychoneurosis do I recall a single instance of the condition following injury to boys at play or in college athletics, boxers, wrestlers or jockeys. This fact, similar to the experience of many others, needs no elaboration.

DIFFERENTIAL DIAGNOSIS

The foregoing discussion of symptoms brings out the considerable difference between the two conditions of organic and nonorganic brain syndromes following trauma. These differences are set forth in the accompanying tables. The mental attitude of the one is different from the other. The neurotic person often resents a diagnosis of minor injury and good prognosis, and his manifest exaggeration and elaboration often produce a heavy strain on the examiner's patience and credulity.

In concussion the picture is one of a general lowering of physical and psychic functions without the emotional, complaining state; frequently distinct euphoria is present. In concussion there is a natural desire for recovery and return to work; this is seen in table 1, which shows that 30 per cent of such patients continued at work with symptoms, in contrast to but 6 per cent in the neurotic group.

The concussion patient often shows amnesia of the accident and for a definite period preceding it and defects of general memory. Concentration is difficult. The neurotic patient is mentally alert. With concussion there is a history of an appreciable period of unconsciousness with more or less severe head injury, often indicated by skull fracture and scalp lacerations. Often the neurotic patient has suffered but a slight blow on the head, and there may be a considerable discrepancy between his description of the accident and the statements of witnesses. Those with concussion spontaneously improve, the neurotic tends to regress. In contrast

to the concussion case, the neurotic shows an inconsistency and variability of symptoms. In concussion there is often a change of character; in the neurotic patient there is an exaggeration of predominant character traits. The course of a concussion case is not affected by settlement of compensation or litigation features; the neurotic person often recovers on such settlement.

Intolerance to heat and alcohol are frequently met in concussion. The neurotic is more apt to show objective signs of nervousness than the patient with concussion.

Twenty-three of 100 patients with concussion presented in table 1 made no complaint of headache. However, headache is an almost constant complaint of the psychoneurotic patient; in my analysis of 100 such cases but three failed to list this complaint, and in these cases the principal symptoms were focused on injury of an extremity. It has been stated that whereas paroxysmal, sharp and localized pain is characteristic of the organic headache, a sensation of constant pressure is typical of the psychoneurotic type. A tabulation of my cases has failed to reveal this distinction, as the headaches in both conditions are variously described as to character, location and duration. This similarity may be explained by the replacement of a true concussion headache by its psychic equivalent in the psychoneurotic person, owing to psychic fixation, and thus also may the difference in incidence be explained.

True vestibular vertigo, often found in the concussion state, is described as a feeling of whirling, and this type may be established by appropriate vestibular functional tests. In the psychoneurotic state the complaint of dizziness is more properly expressed by giddiness.

TABLE 2.—Differential Diagnosis of Major Symptoms

Post-Traumatic Psychoneurotic State (Psychoneurosis Hysteria)	Post-Traumatic Concussion State (Concussion, Traumatic Encephalopathy)
1. Does not wish to work	Wishes to work
2. Depressed, emotional, complaining	Euphoric, aggressive, periods of explosive irritability
3. Mentally alert	Amnesia of injury; memory and concentration difficult
4. Aggravation of inherent personality defects	Changes from original personality makeup
5. Frequently slight injury	Often severe injury, followed by long period of unconsciousness
6. Hysterical symptoms and signs	No hysterical symptoms and signs
7. Exaggeration and elaboration in statement and behavior	No exaggeration or elaboration in statement and behavior
8. Course: tendency to aggravation	Course: tendency to improvement
9. Favorable effect of termination of compensation or of settlement	No effect of termination of compensation or of settlement
10. Multiplicity, changeability, and indefiniteness of symptoms	Constant and precise symptomatology
11. Headache rarely absent	Headache frequently absent
12. Dizziness: giddiness	Dizziness; vertigo
13. No disturbance of tolerance to heat and alcohol	Intolerance to heat and alcohol

The foregoing material describes the contrasting pictures of uncomplicated cases of concussion and psychoneurosis. Obviously, they may coexist in the same patient or be further complicated by organic paralysis from brain laceration and contusion and by malingering. Such a complicated picture may be difficult at times to evaluate, especially in a malingerer. A study of performance in a suspected malingerer when he is unaware of observation is of great value.

Finally, a word as to the responsibility of the physician in the production and recognition of the psycho-

neurotic state. Too often the physician does not realize the suggestibility and apprehension of the ordinary lay person in any circumstance which affects his bodily state or feeling of well-being. An unguarded statement as to the severity of trauma or outlook for recovery, if this carries the idea of any doubt, may precipitate a psychoneurosis. Treatment of the neurotic person for his original injury is often unduly prolonged without the suspicion that his symptoms are mental in origin.

However, the mental origin may be recognized fairly early by the physician in charge of an industrial case, and settlement or final rating of compensation award may be strongly recommended; in this event, responsibility for long-continued treatment without improvement rests on the court or the industrial accident commission referee, who with the commendable intention of protecting the interests of the claimant, refuses to authorize a settlement and insists on further treatment, adopting a "post hoc, ergo propter hoc" attitude. This refusal constitutes a powerful suggestion of serious injury, which falls on fertile ground in the mind of the psychoneurotic, thereby further fixing his neurosis and rendering useless efforts of subsequent treatment.

SUMMARY AND CONCLUSIONS

The term traumatic neurosis should be discarded and replaced by a more fitting and descriptive classification.

After-effects of head injury may be classified as concussion, concussion, psychosis and psychoneurosis, all essentially different conditions.

The post-traumatic concussion state produces reversible changes of brain function which, in severe cases, may become irreversible, with demonstrable pathologic change.

The post-traumatic psychoneurotic state, characterized by fear, suggestion and wishful thinking, is due to the precipitation of psychic complexes, following a period of meditation, in patients presenting inadequate personality traits and subjected to adverse mental influences.

909 Hyde Street.

ABSTRACT OF DISCUSSION

DR. GEORGE W. HALL, Chicago: In cases of concussion the patients are more susceptible to the effects of alcohol. I observed a man with a history of having been able to take alcohol moderately without any disturbances whatever until he became a prize fighter. He was knocked out on one or two occasions and after those incidents his personality changed. At present he is most affable when not under the influence of liquor, but two or three drinks now will make him extremely vicious. On one occasion he threw a milk wagon driver out of his wagon, threw the bottles on the driver and drove off with the car. He drove into a garage, picked up another car and traveled a little farther before he was arrested. He spent about six months in jail for that offense, and a week or two ago he took his mother's new car out and it was found front-first down the stairs of an empty basement as a result of his taking alcohol. Yesterday Dr. Hartman stated that oxygen is the agent for the cure of acute alcoholism. It may be that in these cases of concussion the brain cells are so damaged that they are unable to absorb the oxygen from the blood in the quantities which the brain cells of a normal person can absorb it, and that is so, according to Dr. Hartman, when the person is under the influence of alcohol. I think that point is well taken in Dr. Schaller's paper as one of the differential points between concussion and psychoneurosis. The other point, of course, is the wish fulfillment in the neurotic, whereas patients with concussion do not desire to quit work. I recall another recent instance in which a man worked four months with a headache following an injury, until

finally he suffered such vertiginous attacks that the manager of the concern caused him to lie off from his work. When he came into the hospital he showed none of the signs that one expects to find in cases of psychoneurosis, no sensory disturbances whatever, and his whole ambition was to forget it all and return to work.

DR. SIDNEY I. SCHWAB, St. Louis: I do not know of any way to measure the effect of a head trauma which produces so-called organic changes. Some of the most difficult cases to handle have been cases in which the trauma was insignificant and the long-distance effects, even assuming that they were organically produced, were long and continuous. On the other hand, if we consider the psychoneurosis, we shall have the same difficulty in measuring the effect and violence of the blow or of the trauma in relation to the remote or recent symptomatic results. Whether one calls these after-effect neuroses or concussive syndromes, or whatever designation one chooses to place on them, the question at issue is What is the nature of the damage to the individual? It does not make a lot of difference if the patient is distorted from a personality point of view owing to an organic destruction of brain elements or whether he is distorted from a personality point of view by virtue of the development and evolution of a neurosis. I see no evidence at present by which an organic disease or a neurosis can be differentiated in terms of mechanism and changes or alterations within the neural mechanism. What we are dealing with here in this artificial separation of these two categories of disease is with the method of examination. We do not have delicate enough instrumentations to determine where in between the dividing line, as the author of this paper has so sharply differentiated, organic changes end and other changes begin. While this differentiation clinically is of value, I do not see that it throws any light on the nature of the changes which involve the personality of both the organically affected individuals and those so-called inorganically affected individuals. This type of traumatic disease cannot be differentially diagnosed on parallel symptomatic groups, certainly in any kind of series of cases which have hitherto been published. The percentage of error in personality and personal reaction is so great that the small 200 or 500 cases amounts to no more than imaginative contributions to the truth. This is a valuable paper because it opens up those vital questions which are facing neuropsychiatrists, neurosurgeons and internists the world over, the association and the coordination and penetration of what was formerly called organic changes into the total life of the organism. Our neuropsychiatric duty is to assess the damages to the person and not to assess the damages in points of litigation.

DR. HARRY E. MOCK, Chicago: Dr. Schaller's paper contains material of value to general practitioners, who see a great number of head injuries and first come in contact with the complications following head injuries. It is natural that as neurologists we should discuss the cerebral pathology and the terminology. The chief point, whether we call it "concussion syndrome" or "persistent cerebral contusion," is that something has happened to that individual's brain from the head injury, be it a slight injury or a serious injury, which causes persistence of symptoms. The skull fracture exhibit which we have at this meeting is visited by many doctors from the smaller communities, and the commonest question asked is What would you do in this case? The histories are usually the same: This housewife, this farmer, this school child had a slight injury, a blow, a fall or an automobile accident and remained unconscious two or three hours. Most of these patients are treated in their homes, most of them remaining quiet in bed for a short period, but after a few days of activity they complain of headaches, dizziness and ringing in the ears, they become despondent and they cry easily or are aggressive. Some of these inquiring doctors think the condition is simply mental, others that it is a traumatic neurosis, while others are anxious to know whether there is any remaining pathologic condition in the brain. In my work many cases are referred for examination with the statement from the referring doctor or insurance company that the patient is a malingerer or a traumatic neurotic. About 80 per cent of these will show some neurologic manifestations or evidence of persistent increased pressure by spinal puncture and manometer reading, while the remaining 20 per cent have no signs and belong in the psychoneurotic group. A careful

study of this so-called post-traumatic concussion group reveals incomplete treatment during the acute stage, an unsympathetic attitude and a misunderstanding of the condition of the patient during his convalescent stage by his doctor and his family and, in many instances, a prolongation of the condition into a true psychoneurotic condition by compensation and litigation problems. Too many are prone to consider all the cases as belonging in the latter class. This is wrong, for many a true traumatic syndrome following a head injury continues even after the settlement is made. The majority of these require a regimen of treatment quite similar to that which they should have had during the acute condition, namely, absolute rest in bed, reduction of the persistent increased intracranial pressure, sometimes by lumbar puncture, usually by a carefully guided dehydration program, and, above all, the avoidance of all disturbing influences until their symptoms have abated. Only a few of them will require encephalography and neurosurgical treatment.

DR. R. P. MACKAY, Chicago: It is not a problem as to whether the patient has either structural damage or psychologic damage but as to how much of each he has. That means that we must not only evaluate the extent to which a neurosis may be present but we must attempt to find out, even if a neurosis is present, to what extent there is also an organic lesion. One syndrome is exceedingly common in these cases. I refer to the postural vertigo and headache which at least half the patients with considerable head injury show, and it is so stereotyped that it could not possibly be due to psychologic factors. The patients report that if they lie in a particular position they have rotary vertigo or that turning the head in a certain direction will produce the vertigo. Not infrequently the headache will be brought on by a certain position or movement of the neck or head. This is one more syndrome which seems to indicate that structural changes have occurred. What the mechanism for the production of the syndrome is I do not know, but I am sure it is "organic" in nature.

DR. LEOPOLD BRAHDY, New York: I want to state briefly my experience. I tried lump sum settlements in industrial compensation cases but they proved a failure. I now tell the postconcussion patient that he may have lighter work at his regular wages for a specific period of time; that a job is there for him if he wants to take it; that if not, his compensation will continue; that if he cannot resume his usual work at the end of the specified time he will be put back on compensation. I have had excellent results with this method. The symptoms have not always disappeared (some complain of headaches from one to three years afterward) but these men are working and are in good health. Dr. Schaller said that the onset of psychic symptoms is about three and one-half months after injury. I think my procedure has shown that the important factor in preventing development beyond the organic damage done by the concussion is to get such a patient back to work. That is a form of therapy the beneficial effects of which cannot be obtained by occupational therapy in an institution, useful as that may be in other conditions. Such a patient must get back to his normal environment among his fellow workers, doing something he regards as real work for wages. This procedure has been successful with me. I should like Dr. Schaller to comment on whether in some of these cases the differential diagnosis by laboratory methods, especially encephalograms, isn't undertaken too early. It does not matter whether we find out from two months to six months after an injury that we are dealing with encephalopathy. If the symptoms are psychoneurotic, we do not help a psychoneurotic patient by subjecting him to encephalograms when a delay of a few months will clarify the diagnosis without such procedure. If it is an encephalopathy, we shall know soon enough that we cannot help him.

DR. WALTER F. SCHALLER, San Francisco: In answer to Dr. Hall: It was the question of the significance of traumatic petechial hemorrhages that led me to the consideration of concussion pathology. The majority of these punctiform hemorrhages in brains showing no gross lesions are due to diapedesis and not to rhexis. Such petechial hemorrhages are not lesions which are produced or which cause damage at the time of accident. Patients do not die from petechial hemorrhages, and these are probably not the most important pathologic change in concussion. It was difficult to present a paper on a subject of

this scope and importance in fifteen minutes. Perhaps five years ago I should have accepted Dr. Schwab's position as to the impracticability of a differential classification between the two conditions discussed, but since I have studied the minute pathology of brain trauma and clinically analyzed a large group of cases of both functional and organic nature I have arrived at the conclusion that it is high time that a differential diagnosis be formulated and all these cases, even though their symptoms and signs may be somewhat similar, not be thrown into the grab-bag of what is often called "post-traumatic head syndrome." I am not aware that any such tabulation as I have made has been attempted heretofore. If my tables do not show the differentiations that I believe are possible and desirable between concussion and psychoneurosis, better tables should be prepared. Serious concussion effects may occur from slight injuries in individuals who are particularly vulnerable. In answer to Dr. Brahdy: I consider laboratory methods of undoubted value in differential diagnosis, particularly when we wish to rule out gross lesions and contusions. The cases here reported were seen an appreciable time after injury, and in such cases, and also in those in which the acute symptoms have subsided, I do not consider encephalography contraindicated.

THE PREVENTION OF CAROTENE ABSORPTION BY LIQUID PETROLATUM

ARTHUR C. CURTIS, M.D.

AND

ROBERT S. BALLMER, M.D.

ANN ARBOR, MICH.

It has been shown by several workers¹ that, when rats were fed diets supplying the provitamin carotene, vitamin A deficiencies developed if liquid petrolatum was added to the diets in amounts comparable to the accepted dosage for human beings. Dutcher, Harris, Hartzler and Guerrant² have reported experiments showing that the carotene of a mixture of carotene and liquid petrolatum was not utilized when fed to animals but that the vitamin A of a carotene-free cod liver oil concentrate mixed with liquid petrolatum was absorbed quite readily from the gastrointestinal tract. They believed that the lack of absorption of carotene was due to the greater solubility of the hydrocarbon carotene in the hydrocarbon liquid petrolatum and that vitamin A was absorbed because of the greater solubility of the sterol vitamin A in the sterols of the gastrointestinal tract. Further work by Mitchell³ and by Jackson⁴ confirms the difference in the effect of ingested liquid petrolatum on the absorption of carotene and vitamin A in animals. Dutcher, Harris, Hartzler and Guerrant² have shown that animals eating a diet of known carotene content apparently absorbed most of it, for but little carotene was excreted in the stools. This small amount, however, was constant and did not increase even though the carotene content of the diet was considerably increased. When liquid petrolatum was given to animals on this diet the amount of carotene

excreted in the stools was roughly proportional to the amount of liquid petrolatum ingested.

One of us⁵ has reported experiments on adult patients showing that plain liquid petrolatum given in amounts of 20 cc. before each meal or 20 cc. before the morning and evening meals would lower blood carotene

TABLE 1.—*The Effect of Various Preparations of Liquid Petrolatum, Taken in Amounts of 20 Cc. Three Times a Day Before Meals, on the Blood Carotene Levels of Patients on a Constant High Carotene Diet of 24,089 International Units of Vitamin A*

Preparation	Blood Carotene Determinations, Dichromate Units							
	Diet Only					Diet Plus Liquid Petrolatum Prep.		
	Fast-ing	4th Day	8th Day	11th Day	14th Day	4th Day	9th Day	12th Day
Liquid petrolatum, agar and water....	8.0	11.5	13.0	12.0	12.5	10.5	8.0	6.0
Emulsified liquid petrolatum.....	7.0	8.0	13.0	14.0	14.0	12.0	10.0	7.0
Liquid petrolatum with 0.26% carotene	17.0	19.0	23.0	24.0	25.0	23.0	22.0	21.0
Liquid petrolatum with 0.28% carotene	6.0	9.0	10.0	12.0	12.0	12.0	12.0	12.0

levels previously elevated by a high carotene diet. In each study the patients ate weighed diets of known constant high carotene and caloric values. In part of this experiment the liquid petrolatum was discontinued and only the diet continued. The blood carotene values, which previously had remained constant or even decreased, would rise appreciably. Plain liquid petrolatum in the amount of 30 cc. taken before retiring seemed to us at that time to have little measurable effect on carotene absorption.

Because many human beings obtain much of their vitamin A by conversion of the provitamin carotene into vitamin A and in view of the frequency that one of the many preparations of liquid petrolatum is prescribed for the relief of constipation or as a substitute for fat in a

TABLE 2.—*The Effect of Various Preparations of Liquid Petrolatum, Taken in Amounts of 20 Cc. Twice a Day Before the Morning and Evening Meals, on the Blood Carotene Levels of Patients on a Constant High Carotene Diet of 30,000 International Units of Vitamin A*

Preparation	Blood Carotene Determinations, Dichromate Units							
	Diet Only				Diet Plus Liquid Petrolatum Prep.

reduction diet regimen, it seemed to us important to determine whether a 65 per cent emulsified solution of liquid petrolatum, agar and water and an 80 per cent emulsion of liquid petrolatum would have the same relative effect on removing carotene from the food of the gastrointestinal tract as plain liquid petrolatum. It also seemed important to determine whether liquid

petrolatum, presaturated with carotene both at room and at body temperature, would protect the carotene contained in the food of the gastrointestinal tract.

METHODS

In general, three types of experiments were carried out. In each of the three experiments, four different patients were given diets of constant caloric and carotene values. The diets were weighed and consisted of two menus, which were alternated daily to afford variety. The patients remained on these diets throughout the experiment. The vitamin A value of the daily diet in the first experiment was 24,089 international units of vitamin A. The vitamin A value, expressed in international units, of the second and third experiments was 30,000.

In the first experiment each patient ate a weighed diet for a period of fifteen days. Following this interval the first patient in this experiment was given 20 cc. of a solution of liquid petrolatum, agar and water three times a day before meals. The second patient received the same amounts of a solution of emulsified liquid

TABLE 3.—*The Effect of Various Preparations of Liquid Petrolatum, Taken in Amounts of 30 Cc. Before Retiring, on the Blood Carotene Levels of Patients on a Constant High Carotene Diet of 30,000 International Units of Vitamin A*

Preparation	Blood Carotene Determinations, Dichromate Units										
	Diet Only						Diet Plus Liquid Petrolatum Preparation				
	Fast-ing	3d Day	6th Day	7th Day	9th Day	10th Day	4th Day	5th Day	7th Day	8th Day	10th Day
Liquid petrolatum, agar and water.....	10.0	12.0	13.0	13.0	13.0	13.0

petrolatum. The third patient received the same amounts of a solution of liquid petrolatum saturated with carotene at room temperature (0.26 per cent). The fourth patient received similar amounts of a solution of liquid petrolatum saturated with carotene at body temperature (0.28 per cent). All patients in the first experiment received the various preparations of liquid petrolatum for eleven days. No attempt was made to mix the preparations of liquid petrolatum with the food, but since the liquid petrolatum was given before mealtime there must have been such a mixing in the gastrointestinal tract. Blood carotene determinations were done at intervals throughout all three experiments by the method of White and Gordon.⁶ The mixture of carotene and liquid petrolatum was not unpleasant to taste. It was orange in color with an aromatic odor like fresh raspberries and tasted somewhat like fresh pumpkin.

The second experiment was a counterpart of the first except that before the morning and evening meals the patients were given 20 cc. of solutions of liquid petrolatum, agar and water; emulsified liquid petrolatum; liquid petrolatum with 0.26 per cent of carotene, and

5. Curtis, A. C., and Kline, E. M.: Influence of Liquid Petrolatum on the Content of Carotene in Human Beings, *Arch. Int. Med.* 63: 54 (Jan.) 1939.

6. White, F. D., and Gordon, E. M.: *J. Lab. & Clin. Med.* 17: 53 (Oct.) 1931.

liquid petrolatum with 0.28 per cent carotene. The four patients in the second experiment remained on the diet of 30,000 international units of vitamin A for eleven days and then, in addition to the diet, took one of the several preparations of liquid petrolatum for twenty days.

The third experiment was likewise a counterpart of the first experiment except that, before retiring, when the upper part of the gastrointestinal tract was probably empty, the patients were given 30 cc. of solutions of liquid petrolatum, agar and water; emulsified liquid petrolatum; liquid petrolatum with 0.26 per cent of carotene, and liquid petrolatum with 0.28 per cent carotene. All patients in this group received the diet of 30,000 international units of vitamin A for ten days and the diet plus one of the preparations of liquid petrolatum for eleven days thereafter.

RESULTS

It will be seen in table 1 that all patients had a rise in the blood carotene levels during the period when they were taking only the high carotene diet. However, when either of the solutions of liquid petrolatum, agar and

Chart 1.—A comparison of the effect of 20 cc., taken three times a day, of plain liquid petrolatum, liquid petrolatum, agar and water, emulsified liquid petrolatum, liquid petrolatum saturated at 22 C. with carotene and liquid petrolatum saturated at 37 C. with carotene on the blood carotene levels. The plain and emulsified types of petrolatum have about the same relative effect. Liquid petrolatum, presaturated with carotene at room temperature, slightly protects the ingested carotene. When liquid petrolatum presaturated with carotene at body temperature is given, the blood carotene level remains constant.

water or emulsified liquid petrolatum was given in amounts of 20 cc. before the three meals the blood carotene levels promptly fell. When a solution of liquid petrolatum with 0.26 per cent carotene was given the blood carotene level remained more constant than with the other two preparations, thus partially maintaining the higher blood carotene level reached when the high carotene diet alone was eaten. When a solution of liquid petrolatum with 0.28 per cent carotene was given, the blood carotene level remained constant.

Table 2 again shows the rise in blood carotene values which occurred when the diet alone was eaten for a period of eleven days. When 20 cc. of either the solution of liquid petrolatum, agar and water or emulsified liquid petrolatum was taken for a period of twenty days before the morning and evening meals, the blood carotene fell to a level lower than the original in the first instance and just short of the original level in the second instance. When a solution of liquid petrolatum with 0.28 per cent carotene was given, the blood carotene level rose three dichromate units in twenty days.

Table 3 shows that when 30 cc. of solutions of liquid petrolatum, agar and water, emulsified liquid petrolatum, liquid petrolatum with 0.26 per cent carotene, or liquid petrolatum with 0.28 per cent carotene is used nightly for eleven days following a period of ten days on constant diets of 30,000 international units vitamin

Chart 2.—When 20 cc. of the same preparations is used twice a day before meals the same relative effects are noted as in chart 1.

A, the effect of the petrolatum on the absorption of carotene is variable. The administration of the solution of liquid petrolatum, agar and water caused no reduction of the blood carotene level. The solution of emulsified liquid petrolatum possibly caused a slight reduction of the blood carotene level. This slight reduction was also evident when plain liquid petrolatum containing an added 0.26 per cent carotene was admin-

Chart 3.—When the five different preparations of liquid petrolatum are given in amounts of 30 cc. before retiring, none have any marked effect on blood carotene levels except the preparation of liquid petrolatum presaturated with carotene at body temperature (37 C.). The increase in blood carotene levels when this preparation was given suggests that even 30 cc. of plain or emulsified liquid petrolatum given before retiring affects the ability of the intestinal tract to absorb carotene from ingested food.

istered. When liquid petrolatum with added carotene in amounts of 0.28 per cent was taken, the blood carotene level actually rose.

COMMENT

The results of the experiments listed show that solutions of liquid petrolatum, agar, water and emulsified liquid petrolatum taken in amounts of 20 cc. three times a day before meals or 20 cc. twice a day before

the morning and evening meals interfered with the transportation of carotene across the epithelium of the intestine, if the fasting blood carotene levels may be used as an index for such absorption. Liquid petrolatum, saturated with carotene at room temperature (0.26 per cent) and taken in similar amounts still interfered with the carotene absorption from the food of the intestinal tract. When liquid petrolatum saturated with carotene at body temperature (0.28 per cent) was taken in amounts of 20 cc. either three times a day or twice a day before meals, the blood carotene levels remained constant or even increased slightly.

The effect of the two emulsified types of liquid petrolatum was not striking when taken in amounts of 30 cc. before retiring. The 0.26 per cent carotene saturated liquid petrolatum also seemed to have little effect. But when the effect of these three preparations are compared with the 0.28 per cent carotene saturated liquid petrolatum, it suggests that even in doses of 30 cc. nightly liquid petrolatum interferes with the organism's ability to absorb carotene from the ingested food.

In a previous experiment one of us⁶ showed the effect of 20 cc. of a plain liquid petrolatum taken three times daily, twice daily and in amounts of 30 cc. taken before retiring on carotene absorption from ingested food. If the results of these experiments are compared with the effects of similar doses of liquid petrolatum, agar and water, emulsified liquid petrolatum, and 0.26 per cent and 0.28 per cent carotene saturated liquid petrolatum (charts 1, 2 and 3)⁷ it is apparent that the emulsified types of liquid petrolatum remove about the same amount of carotene from the food of the intestinal tract even though the oil content of the emulsified types of liquid petrolatum is 65 per cent and 80 per cent respectively. When added carotene is present in amounts of 0.26 per cent at 0.22 C. the absorption of carotene by liquid petrolatum from ingested food is reduced, but it still occurs. When liquid petrolatum saturated with carotene at body temperature (0.28 per cent at 37 C.) is given, the ingested carotene bearing foods are protected and the blood carotene levels do not decline.

It was not apparent at first why liquid petrolatum saturated with carotene at room temperature failed to protect the carotene of ingested food while saturation at body temperature did so, for the difference in saturation was only 0.02 per cent. Is is easily explained, however, if one expresses the saturation of liquid petrolatum with carotene at these temperatures in international vitamin A units. At body temperature it requires 280,000 international vitamin A units of carotene to saturate 60 cc. of plain liquid petrolatum. At room temperature it requires 240,000 international vitamin A units of carotene to saturate 60 cc. of plain liquid petrolatum. This difference of 40,000 units in the saturation of liquid petrolatum with carotene at room and body temperatures is greater than the total number of vitamin A units in our high carotene diets. These calculations also show the relative unsaturation of liquid petrolatum as far as carotene is concerned and also make it understandable why even 30 cc. of liquid petrolatum interferes with the absorption of carotene by the gastrointestinal tract.

CONCLUSIONS

1. Two emulsified types of liquid petrolatum, the first containing 65 per cent liquid petrolatum, 1 per cent agar and 34 per cent water, and the second containing 80 per cent liquid petrolatum, 1 per cent agar and 19

per cent water, were given in amounts of 20 cc. three times a day before meals, twice a day before meals and 30 cc. before retiring. The effect of these emulsified preparations of liquid petrolatum on the absorption of carotene from the gastrointestinal tract was compared with the effect of similar doses of plain liquid petrolatum and found to be comparable.

2. Plain liquid petrolatum, saturated at room temperature with carotene (0.26 per cent at 22 C.) still removes carotene from ingested food, but in lesser amounts.

3. Plain liquid petrolatum saturated with carotene at body temperature (0.28 per cent at 37 C.) prevents the petrolatum from removing carotene from the food in the gastrointestinal tract.

STREPTOCOCCUS VIRIDANS BACTEREMIA FOLLOWING EXTRACTION OF TEETH

A CASE OF MULTIPLE MYCOTIC ANEURYSMS IN THE PULMONARY ARTERIES; REPORT OF CASES AND NECROPSIES

H. D. PALMER, M.D.

AND

MYRNA KEMPF, B.A.

ROCKFORD, ILL.

Streptococcus viridans is constantly present in alveolar infection and frequently enters the blood stream when these infected areas are traumatized. Other organisms are less regularly present and *Streptococcus viridans* enters the blood stream from this focus much more frequently than all others combined. The resulting bacteremia is usually transient, but a knowledge of the frequency and mechanism of its occurrence is essential to an understanding of the pathogenesis of the secondary foci of localization—notably subacute bacterial endocarditis. It is our purpose in this paper to reveal our experience as to the frequency of bacteremia following tooth extraction and to portray the consequences incident thereto through the report of (1) well studied clinical cases with postmortem examinations and (2) bacteriologic examination of the teeth and blood of persons undergoing tooth extraction.

REPORT OF CASES

CASE 1.—*History*.—A white man, aged 44, a patient of Dr. Arthur Pearman, had always enjoyed satisfactory health in spite of the known presence of a congenital cardiac lesion. Because of the congenital anomaly of the heart he had been spared strenuous activities but had been able to carry on in ordinary school and business life without physical complaint. Immediately after the extraction of several teeth in December 1936 he complained of weakness, sweating and mild prostration and had a fever of the septic type. The morning temperature was usually normal, but there was a temperature of from 100 to 101 F. each evening. The pulse was 110 and the blood pressure 138 systolic, 75 diastolic. The area of cardiac dullness was enlarged approximately 2 cm. to the left. There was a loud harsh roaring "machinery murmur," with its greatest intensity at the second and third interspace to the left of the sternum. In spite of the great intensity, it was not widely transmitted and did not extend more than 5 cm. in any direction from the area of the pulmonic valve. The murmur was systolic in time and continued throughout most of the diastole. The spleen was palpable but not painful. The hemoglobin was 11 Gm.; red blood cells numbered 4,290,000 and white blood cells 8,350. Blood culture yielded *Streptococcus viridans*.

From the Laboratory of the Rockford Hospital.

EXTRACTION OF TEETH—PALMER AND KEMPF

1789

The course had a duration of one year and there was but little variation. Petechiae in the skin or mucous membranes were never observed. He had drenching night sweats, afternoon fever and a gradually developing pallor. Cyanosis was not observed. Only during the last four weeks did he complain of pain. This was in the "lungs" and he was unable to lie on either side. Positive blood cultures for *Streptococcus viridans* were obtained on each attempt.¹ The patient died in December 1937 with evidence of increasing cardiac failure. The clinical diagnosis was subacute bacterial endocarditis implanted on a congenital anomaly.

Necropsy.—There was a small amount of fluid in each pleural cavity. The heart was surrounded by 500 cc. of serofibrinous exudate and the pericardial surfaces had a shaggy "bread and butter" appearance. The heart weighed 550 Gm. and had a transverse diameter of 16 cm. The right side was especially enlarged. The pulmonary artery was greatly enlarged. The pulmonary leaflets were thickened by large gray vegetations and thrombi. The valve was incompetent. Vegetative masses extended upward on the wall of the pulmonary artery, and on the left lateral wall there was a mycotic aneurysm 4 cm. in diameter. This was partially lined by clot, but the wall of the artery was completely destroyed and the pericardium was sacculated. This lesion explained the origin of the pericarditis. *Streptococcus viridans* was present in the pericardial exudate. The orifice of the left pulmonary artery was at the upper limit of this aneurysm. Anterior to this opening was the orifice of a patent ductus arteriosus 1.5 cm. in diameter (fig. 1). There was much calcification of the wall of the ductus arteriosus and of the adjacent areas in the pulmonary artery and aorta. The lungs were edematous and relatively atelectatic throughout. Dissection of the pulmonary arteries revealed multiple mycotic aneurysms (figs. 2 and 3). They varied in diameter from a few millimeters to 3 cm., and most of them were occluded by fibrinous clot. None of them showed evidence of suppuration.

Fig. 1 (case 1).—Probe passing through patent ductus arteriosus. Vegetations on pulmonic valve and wall of pulmonary artery. Mycotic aneurysm in the pulmonary artery. Pericarditis.

Embolitic phenomena were not demonstrated in any part of the greater circulation. Changes in the organs were those that accompany sepsis and chronic passive congestion. The spleen weighed 620 Gm. and measured 20 cm. from pole to pole. It was firm and had the uniform red color of reticulo-endothelial hyperplasia. Microscopically the aneurysms showed the internal

elastic membrane ruptured and the sac formed mostly of adventitia. In the kidneys a few glomerular capillaries contained large numbers of polymorphonuclear leukocytes, and still fewer showed pericapsular areas of inflammation. The picture of multiple embolization of the glomeruli was not present. Microscopic examination of other tissues added nothing to the gross interpretation.

Fig. 2 (case 1).—Mycotic aneurysms in radicles of the left pulmonary artery. Mycotic aneurysms at the base of the pulmonary artery (closed by stitches).

In spite of a congenital cardiac lesion, the patient subjectively was entirely well until he had a number of teeth extracted. Signs of sepsis developed immediately and *Streptococcus viridans* was recovered from his blood. Embolization within the pulmonary circulation resulted in the development of multiple mycotic aneurysms. Embolization within the greater circulation was possible through the patent ductus arteriosus but apparently did not occur.

CASE 2.—History.—A white woman aged 35, a patient of Dr. Arthur Pearman, had rheumatic fever at the age of 4 years, with several indefinite but probable recurrences during childhood and adolescence. Tuberculous cervical adenitis developing in 1926 was successfully treated by x-rays. In 1928 therapeutic abortion was performed because of high grade mitral stenosis. In January 1937 she was under treatment for oral sepsis of a pyorrheal nature and for repair of her teeth. She had gone to the dentist feeling well. Procaine hydrochloride was injected into the gums. She returned home, experienced a chill, and her temperature reached 104 F. The chills were repeated; the fever was high and of the septic type; drenching sweats debilitated her. She became mildly icteric and obviously very ill. Her pulse ranged around 120. The blood culture yielded 260 colonies of *Streptococcus viridans* per cubic centimeter of blood. The physical manifestations were those of mitral stenosis and aortic regurgitation; a tender spleen was palpable 3 cm. below the left costal margin; numerous petechiae appeared in the skin and conjunctivas, and tender finger and toe pads developed

1. Haden, R. L.: Experimental Evidence of Relation of Dental Infection to Systemic Disease, *J. Kansas M. Soc.* 26: 41-47 (Feb.) 1926.

with splinter hemorrhages. The hemoglobin was 8.5 Gm.; red blood cells numbered 3,300,000 and white blood cells 16,200. Urine contained 1 plus albumin and a trace of chemical blood, and the sediment was loaded with pus cells.

The course had a duration of six months. There were frequent showers of emboli to the spleen and into the skin. A high grade of sepsis with increasing evidence of cardiac failure characterized her illness.

Fig. 3 (case 1).—Close view of mycotic aneurysms in the radicles of the left pulmonary artery shown in figure 2.

Necropsy.—Petechiae in the skin and mucous membranes, slight clubbing of the fingers and slight dependent edema were found on external examination. There was fluid in all the cavities. The pericardial sac was filled. It measured 20 cm. in diameter and reached the lateral wall of the chest on the left. The heart measured 12 cm. in transverse diameter and weighed 310 Gm. The left auricle was enormously enlarged, measuring 10 cm. in depth. Along the posterolateral wall of this cavity were a number of coarse thrombi and smaller vegetations varying from gray to red. The mitral valve was greatly thickened and the chordae tendineae were shortened (fig. 4). The leaflets were fused and the orifice, which was fixed and measured only 1 cm. in diameter, was closed by a fresh thrombotic mass which was continuous with older gray vegetations on the valve. The aortic valve presented similar changes. There was an old rheumatic lesion and the ventricular surfaces were studded with vegetative masses. The edges of the cusps showed moderate ulceration. The spleen weighed 480 Gm. It showed hyperplasia of the reticulo-endothelium and numerous areas of infarction in various stages of development. The kidneys weighed 320 Gm. They were gray, mottled with red streaks. Microscopically they showed multiple embolization of the glomerular capillaries. The changes in the other organs were those of sepsis and chronic congestion.

In this case, though no teeth were extracted, there is a history of very closely connected onset of sepsis with dental manipulation, including the traumatization incident to injection of procaine hydrochloride. A chill with high fever marked the onset almost immediately after the manipulation of the focus. An old rheumatic lesion furnished the "suitable soil" for implantation. Richards'² experiments are of interest in relation to this case. He obtained positive blood cultures in three of seventeen cases following massage of the gums. About the same percentage of his cases yielded positive blood cultures after massage of the tonsils. In two of his cases there was a chill following the massage of the tonsils. The condition is apparently comparable to catheter fever.

CASE 3.—History.—A girl aged 18 years, a patient of Dr. H. D. Countryman, had rheumatic fever with endocarditis at the age of 8 years. Following the acute attack she had evidence of mitral stenosis with insufficiency. At the age of 14 some teeth were removed and a dental bridge was fitted without

accident. Three years later she returned to the dentist for "extensive repair work." Her health at this time was "as well as usual." Several of the teeth were devitalized and filling of the root canals was undertaken. Most of the work was done under infiltration with procaine hydrochloride. Within a few days after this dental program had been started, she complained of chills, fever, night sweats and loss of strength. She continued to keep dental appointments for a week but then found it necessary to give up. Painful finger and toe pads developed. There was a harsh systolic murmur over the mitral area, with a presystolic thrill. The murmur was transmitted to the axilla. The border of the left side of the heart was outside the mid-clavicular line. The spleen was palpable and tender. It reached 4 cm. below the costal margin. The hemoglobin content was 65 per cent; red blood cells numbered 3,330,000 and white blood cells 5,150. Blood cultures taken on three successive days yielded pure cultures of *Streptococcus viridans*. There were more than 50 colonies per cubic centimeter of blood. Cultures taken bimonthly were positive throughout the course, which lasted five months, ending fatally. The urine contained small amounts of albumin and a small number of pus cells throughout the course.

Necropsy.—The pleural and peritoneal cavities contained large amounts of fluid. The pericardial sac was obliterated by dense fibrous adhesions. The heart weighed 550 Gm. and presented marked enlargement of the left auricle and both right chambers. The mitral leaflets were thickened and fused and the chordae tendineae were thickened and shortened. Large vegetative masses were found on this valve and extended from it upward on the septal wall of the left auricle and downward over the

Fig. 4 (case 2).—Vegetative endocarditis engrafted on scarred mitral valve.

papillary muscles. The left coronary artery was occluded near its orifice by an embolus made up of vegetative material. Microscopically the capillaries of the kidney glomeruli contained emboli.

This child, with a healed rheumatic lesion in the mitral valve, had the onset of a septic course during the progress of extensive dental repair under local anesthesia. Death was due to coronary embolism.

2. Richards, J. H.: Bacteremia Following Irritation of Foci of Infection, J. A. M. A. 99: 1496 (Oct. 29) 1932.

CASE 4.—History.—A man aged 60, a patient of Dr. Anna Weld, experienced chills and fever and was confined to his home for six weeks following the extraction of his lower teeth. Prior to this he had complained of "heart trouble," but there is no accurate description of a preexisting cardiac lesion. He had recovered sufficiently to return to work when removal of the teeth from the badly diseased upper gum area was decided on. This experience was followed immediately by chills, afternoon fever, lassitude, loss of strength, loss of weight and night sweats. *Streptococcus viridans* was recovered from the blood stream. There was physical evidence of a mitral lesion. The course was septic and he died within six months. Necropsy was not permitted.

The clinical history suggests that bacteremia was established following the first extractions, with possible recovery. Progressive fatal bacteremia with evidence of *Streptococcus viridans* endocarditis followed immediately on the massive extraction of the upper teeth.

BACTERIOLOGIC STUDY: RESULTS OF BLOOD CULTURES FOLLOWING EXTRACTION OF ONE OR TWO TEETH

In an unpublished bacteriologic study of the roots, root canals, pulp and periapical tissues of a large number of diseased deciduous teeth extracted in the Childrens Hospital in Iowa City in 1927 and 1928, we were impressed by the presence, usually in pure culture, of *Streptococcus viridans* in more than 90 per cent of the teeth from which cultures were taken.³ Beta-hemolytic streptococci and diphtheroid bacilli were found in this work. The teeth were removed with technic as nearly aseptic as possible; the root was separated with a sterile saw and placed in 70 per cent alcohol for from three to five minutes. It was then washed with two changes of sterile physiologic solution of sodium chloride and dropped into a tube of deep meat broth (1 per cent dextrose fresh veal infusion broth with a cube of beef at the bottom of each tube, p_H 7.4). Subsequently the broth was streaked on blood agar. It has been our experience and the experience of others⁴ that adult teeth, when diseased, yield the same high percentage of *Streptococcus viridans*.

During the past year, with Joseph A. Hopkins, D.D.S., cooperating, we have made blood cultures on eighty-two patients who had dental extractions under local anesthesia. We purposely selected patients who were not to have more than two teeth removed and made no attempt to determine whether or not there was infection in the apical areas. Okell and Elliott⁵ in 1935 reported a very high percentage of positive blood cultures immediately after massive extraction of teeth from highly diseased alveoli. We were interested in learning the result of blood cultures in persons who have one or two teeth pulled for any reason. The teeth in our series were removed because they were dead, diseased beyond repair or for other reasons not related to this study. All the patients had negative cultures of blood taken immediately before operation. Fourteen of the eighty-two, or 17 per cent, gave positive cultures with blood taken immediately after the extraction. In thirteen of the fourteen positive cultures the blood was sterile ten minutes later. The other bacteremic case yielded organisms in the circula-

tion ten minutes after the operation. The patient, a man aged 65, suffered from arteriosclerotic heart disease. He left the community soon after the extraction and passed out of our control. We learned that he had a continuous fever and died after several weeks. A necropsy was not performed. Elevation of temperature did not develop in the other thirteen cases of transient bacteremia. In eleven of the cases yielding positive blood cultures the organism was *Streptococcus viridans*; in two *Staphylococcus aureus* (hemolytic) was cultured, and in the remaining case a diphtheroid bacillus was recovered.

COMMENT

Streptococcus viridans, admitted to the blood stream by extraction of teeth, occasionally localizes in areas of the vascular system other than the heart. The following record is an example: A woman aged 59 who suffered from hypertensive heart disease had several teeth extracted. This was followed by severe occipital headache and dizziness. There was a rise in temperature, which within a week reached a level of 104 F. Coma developed and she died eight days after the extraction. A ruptured mycotic aneurysm of a sclerotic cerebellar artery was found at necropsy. *Streptococcus viridans* was recovered from the brain tissue.

From the oral and pharyngeal mucous membranes there are two paths by which bacteria break through the protective lining of the dental arches. Miller⁶ writes: "The first is by bacterial penetration through defects in the crown of the tooth produced by caries, erosion or accident. The second break is in the epithelial covering occurring at the junction of the gum and the crown of the tooth." By the first route the pulp and periapical area become infected. The second route results in pyorrheal pockets and infection of the bone of the alveolar process; the cementum becomes exposed and in severe cases the apical area is reached. The dental pulp then becomes strangulated and infected. It is evident, therefore, that the apical area and pulp may be reached by either route. The second route probably is frequently considered important to the health of the teeth but too infrequently as a portal of entry in the pathogenesis of distant infection.

Rosenow,⁴ Henry and Doyle⁴ and many others have recovered streptococci from a high percentage of pulpless teeth, irrespective of whether roentgenograms were positive or negative for periapical infection. In 1926, Russell Haden¹ published a very careful study of cultures from the periapical tissue of 1,500 teeth. Streptococci were present in 92.5 per cent, staphylococci alone in only 1.3 per cent, gram-positive bacilli alone in 3.8 per cent.

Okell and Elliott⁵ found that a transient *Streptococcus viridans* bacteremia occurred in eighty-four (60.9 per cent) of 138 patients who underwent dental extraction. In cases of severe alveolar infection, 75 per cent of the patients who underwent multiple extractions had positive blood cultures immediately after the operation. In general, these authors found that the occurrence and degree of bacteremia depended on the severity of the alveolar infection and the amount of damage done at the operation. That the bacteremia was of short duration was shown by the fact that blood cultures taken in all their cases ten minutes or more after the operation was completed remained sterile. In this series Okell and Elliott also found twelve positive blood cultures in blood taken before operation from 110

3. This work was done in the Department of Pathology and Bacteriology of the State University of Iowa College of Medicine. The department was directed by Dr. G. H. Hansmann.

of the patients. In other words, 10.9 per cent had bacteremia irrespective of operative procedures. They speak of this as a "leak" of bacteria into the blood stream from the focus and quote Lewis and Grant as referring to an "almost physiological entry" of organisms into the blood stream of the average person.

The direct historical relation between foci in the mouth and the onset of subacute bacterial endocarditis has been stressed by some writers.⁷ This group of authors report twelve cases of subacute bacterial endocarditis with onset following the extraction of teeth. Necropsies were not performed in nine of the twelve cases, and bacteriologic studies were not made in six.

Three of our four case reports are from a group of twelve cases in our necropsy records. Of the twelve, two additional cases gave suggestive histories of onset following manipulation of infected alveoli. The other records are not complete in this respect; it is necessary that the history taker be conscious of this possibility if accurate records are to be made.

Cecil⁸ has reviewed the bacteriologic studies reported and has suggested clinical application of the information gained. Carr⁹ has reviewed the literature. He writes "The unfavorable or harmful results following the surgical treatment of such foci, especially in connection with cardiac disease, are events of sufficient importance to impose on us the duty of caution." Evidence that the teeth and tonsils are of first importance as portals of entry for this organism has become predominant. This evidence has provoked serious thought and makes the treatment of oral sepsis in the presence of a debilitating condition, particularly a cardiac lesion, a serious problem. A more widespread understanding of the simple fact that organisms are easily disseminated from such a focus is necessary for better treatment.

SUMMARY

Seventeen per cent of a group of eighty-two patients who had not more than two teeth extracted had transient bacteremia. In 13.4 per cent the organism was *Streptococcus viridans*. In four cases of subacute bacterial endocarditis the onset of septic symptoms dates from the time of dental manipulation.

Bacteremia is present in an appreciable percentage of cases of severe oral sepsis independent of operation.⁶ Organisms "leak" into the circulation from such foci. Traumatization of the diseased alveoli laden with *Streptococcus viridans* causes dispersion of these organisms through the blood stream in a high percentage of cases. The percentage is roughly parallel to the severity of the infection in the gums and to the extent of the operative procedure. This may be purely mechanical dispersion rather than invasion. In persons with a normal vascular system and a normal defense mechanism, this form of bacteremia is relatively unimportant. The circulation is usually cleared of the invaders within

a few minutes.¹⁰ Hypersusceptibility of the tissues due to long continued oral sepsis is speculated on by Cecil.⁸ In persons who have preexisting rheumatic valvular lesions or congenital defects in the heart, localization of the organism on such vulnerable areas during the transient bacteremia, which so often follows dental operations, may herald the beginning of an engrafted bacterial endocarditis.

A CLINICAL STUDY OF ACNE IN UNIVERSITY STUDENTS

FRANCIS W. LYNCH, M.D.

ST. PAUL

The etiology of acne remains obscure in spite of the investigative opportunity afforded by the high incidence of this disease. It has been studied from the point of view of specific infection, focal infection, allergy and disturbed metabolism of carbohydrates, fats and halogens, but none of these factors have been accepted as a specific etiologic agent. Recent interest has been directed toward a relation with the endocrine system, suggested by the onset of acne at puberty and its usual disappearance with sexual maturation, the frequent exacerbation with the menses and its reported absence in eunuchs.

A number of observers have demonstrated abnormal amounts of estrogenic or androgenic principles in the blood or urine of patients with acne. Although these studies suggest a relationship between acne and the endocrine system, the individual variations are considerable and there must be some doubt as to the significance of averages among groups of patients when there is so little uniformity within each group. These apparent hormonal deficiencies can as yet be regarded only as associated with acne rather than as a demonstrated cause of the disease. Particularly disappointing are the relatively poor results of treatment of acne with estrogen or androgen.

It is the opinion of many that acne is often accompanied by clinical evidence of endocrine disease, and this association is regarded as etiologically significant. It has also been said that acne is frequently accompanied by menstrual irregularity, but no one has recorded sufficient clinical evidence to prove a causal relationship.

In order to determine how frequently acne is associated with other clinical phenomena, observations were made on three groups of students at the University of Minnesota. Routine physical examination of students at the time of their registration in the university provides a large amount of general data, but there is a lack of detailed information as to the condition of the hair and skin; the presence or absence of acne is recorded by the staff physicians but its character, severity and extent are not accurately described. In the first and largest group of students, these data were analyzed to determine the relation between acne and the character of the menses in 3,119 cases and the relation to the form of the body and the weight in 4,235 cases.

10. Progressive septicemia due to highly virulent organisms is an occasional accident following dental operations but is not considered in this paper.

From the Student Health Service, Dr. Ruth Boynton, Director, and the Division of Dermatology, Dr. H. E. Michelson, Director, University of Minnesota.

Read before the Section on Dermatology and Syphilology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

In the second group were 481 consecutive new students subjected to more careful dermatologic examination. Their records were reviewed for additional diagnoses resulting from the general examination as well as for the weight and form of the body and the character of the menses. They were questioned as to their habits of facial and scalp hygiene and the frequency of bowel movement. In each case the scalp was examined for evidence of seborrhea and the face and trunk were observed for acne. Although no attempt was made to count the individual lesions, the acne was graded as mild, moderately severe or severe. The duration, extent and distribution of the eruption were also recorded. The color and texture of the hair were similarly classified by practical rather than scientific standards.

In the third group were students who came to the health service for treatment. Of these patients, 251 were studied in the same manner as those in group 2. For an additional 120 students applying for treatment the basal metabolic rate was determined, and they were carefully questioned as to the character of the menses and the course of their eruption. Repeated changes in the length of the menstrual cycle were regarded as significant if there was a variation of more than three days from the accepted average of twenty-eight days. Since there is considerable doubt as to the endocrine influence in dysmenorrhea, this symptom was reviewed separately and was disregarded unless it required going to bed each month. A menstrual flow having a duration of three days or less was regarded as significant oligorrhea.

INCIDENCE OF ACNE

The incidence of acne as recorded on the routine examination was of little value because of the large number of examiners and the tendency for minor degrees of the disease to be ignored by some of the physicians. Among the 481 students undergoing the special examination on admission, the boys were subject to the disease more often than the girls and the severity of their eruption was considerably greater. This increased incidence was observed at each age level from 17 to 21 years.

TABLE 1.—Incidence of Acne Among 481 Students

	No Acne, per Cent	Acne, per Cent		
		1+	2+	3+
Boys (229).....	43	29	24	4
Girls (252).....	54	31	14	1

Since all these patients were university students, the incidence at various ages does not give a true picture of the course of acne. The median age of the boys was 19 and of the girls 18 years. The fact that the median age in the severe cases was no higher than that in the mild ones suggests but does not prove that severity is not related to the duration of the disease. The higher incidence among boys may be due only to the age of the group; acne develops at a later age in boys than in girls.

CHARACTER OF THE ERUPTION

A greater severity of involvement among the boys was further demonstrated by the character and distribution of the eruption. Pustular forms of acne were more common among boys, while papular eruptions were present equally in the two sexes.

In a group of 277 boys and 219 girls the trunk was involved much more often among the boys, but in both sexes the face was the most common site, with the back next and the chest least often involved.

COURSE OF THE DISEASE

It was found that the course of acne was seldom regular and that irregularity was about equally common to boys and girls. In most cases having an irregular course, the exacerbations were associated with the menses. Abnormal menses were twice as common among girls having such a premenstrual flare-up.

RELATION TO BODY BUILD

In a group of 4,235 boys and girls whose body build was classified as hypersthenic, sthenic or asthenic there

TABLE 2.—Relation of Acne to Body Build Among 4,235 Students

		Without Acne, per Cent	With Acne, per Cent
Boys	Hypersthenic.....	8	9
	Sthenic.....	86	84
	Asthenic.....	6	7
Girls	Hypersthenic.....	10	12
	Sthenic.....	52	56
	Asthenic.....	38	32

was no relation between the form of the body and the presence of acne. The boys showed fewer variations from the sthenic build than did the girls.

For the group of 666 students examined more carefully, similar observations were recorded. The only statistically significant variation was the observation that asthenic girls are unlikely to suffer from severe forms of acne.

The classification of body build as hypersthenic, sthenic or asthenic is admittedly not the most satisfactory from an endocrine standpoint, but it was thought that significant endocrine abnormalities might become evident because of the large number of students examined. Since there is no doubt that variations in endocrine function may affect the form of the body, probably in relation to the thyroid, pituitary, adrenal and gonadal secretory activity, it may be worth while to review another group of patients following more accurate morphologic classification such as has recently been established for girls.¹

RELATION TO BODY WEIGHT

Deviation from normal standards of weight are occasionally but not always an indication of endocrinopathy. In these records a variation from standard averages greater than plus or minus 10 per cent was regarded as abnormal. In neither series of students were significant differences noted with reference to the presence or the severity of acne. (Regardless of the presence or absence of acne, girls were likely to weigh less and boys more than the "normal" figures.)

BASAL METABOLIC RATE

Of the methods used for determining endocrine abnormality, the metabolism test is the only one which allows accurate comparison of the results with accepted standards. This test is chiefly a measurement of the activity of the thyroid gland but abnormal rates may also result from disease in other glands.

It is well known to students of metabolism that girls utilize less energy than boys. This difference is taken

1. Bayer, Leona M.: Build in Relation to Menstrual Disorders and Obesity, *Endocrinology* 24: 260 (Feb.) 1939.

into account in the establishment of normal standards of metabolic rate as expressed in percentages. Thus, although ± 0 per cent represents a lower level of metabolic activity in girls than in boys, the figure is in each case the normal or average for other persons of the same sex, age and body area. This point is emphasized because in a series of forty-three boys and seventy-seven girls with acne the average basal metabolic rate of the girls was significantly lower than that of the boys. Rates deviating from the normal by more than ± 10 per cent were equally numerous in the two sexes, but in the girls more of the abnormal rates were low and

mal menses was considerably higher (40 per cent). This figure is in agreement with the statements of many writers but it is not known whether this represents a significant difference from girls without acne. The facts could be obtained only by requiring a larger group to keep a written record for at least six months. In this smaller series of girls, the incidence of abnormal menses was apparently greater as the severity of the acne increased.

TEXTURE AND COLOR OF THE HAIR

Texture of the hair was investigated because it was thought that the size of the hair follicles would be likely to influence the tendency to acne. Fine hair was much more common than coarse hair in the entire group. It was noted that severe acne was slightly less common in girls with fine hair, but statistical methods indicated that the amount of variation was probably not significant.

There was no relation between the color of the hair and the presence of acne. In Sallenbach-Keller's series⁴ there was an increased incidence of acne among those with darker hair, but Cunningham and Lunsford⁵ in records of the complexion found that brunettes had a slightly better chance of escaping acne.

ASSOCIATION WITH SEBORRHEA, HYGIENE, CONSTIPATION AND FOCI OF INFECTION

Boys were noted to have seborrhea more often than girls. In both sexes seborrhea was more common among those with acne and the incidence increased with the severity of the acne.

The results of inquiry as to the frequency of washing the face indicated that girls without acne wash less frequently, as had been noted by Hinrichsen and Ivy.⁶ This lack of attention is perhaps a natural result of lack of need for attention. Among the boys there was no association between the incidence of acne and the frequency of washing.

The incidence of constipation was negligible in both sexes whether or not acne was present.

TABLE 4.—Basal Metabolic Rates of Forty-Three Boys and Seventy-Seven Girls

	Boys	Girls ^a

+1 to +10%.....	18	21
Higher than +10%.....	8	10
	26 (60%)	31 (42%)

* A result of $\pm 0\%$ was reported for two girls.

A wide variety of additional diagnoses was recorded but the only condition which appeared to have any significance was focal infection of the nose or throat, which was much more common in boys than girls. It is possible that this infection is related to the increased incidence of papular and particularly pustular lesions in boys as compared with girls.

THERAPY

The age of onset and the course of acne suggest that this disease is related to the endocrine system, and chemical determinations of estrogen and androgen in

TABLE 3.—Relation of Acne to Body Build Among 666 Carefully Examined Students

	Asthenic.....	12	23	4	0

in the boys more were high. When the patients were not classified by sex, those having plus rates were equal in number to those having minus rates.

In boys or girls plus rates were twice as common among those having involvement of the trunk as among those whose acne was limited to the face. When the eruptions were graded as to severity but not extent, the records suggested that higher rates were found in the more severe cases among both boys and girls, but statistical methods of analysis failed to demonstrate that this apparent trend was significant. A larger series might clarify this point.

RELATION TO THE MENSES

One of the best clinical means of estimating the normality of endocrine function is the menstrual history. Since the patient's statement of character of the menses is usually accepted by the physician, it is unfortunate that such histories are not dependable. It has been shown in college students that at least one third have only an inaccurate knowledge of their menstrual cycle.² Thus it is obvious that no menstrual history or group of histories can provide conclusive evidence unless the patients have kept written records.

Since any significant difference might become evident because of the large number of persons studied, these data based on routine questioning of 1,214 girls with acne and 1,905 without acne are reported, even though probably inaccurate. Analysis of the percentage of subjects with each type of menstrual difficulty showed striking agreement in the two groups. Thirteen per cent gave a history of irregularity, menorrhagia or amenorrhea, and an additional 4 per cent in each group suffered from severe dysmenorrhea. Further subdivision of these students according to age did not significantly change the proportions, perhaps because only a relatively small number were over 21 years of age (8 per cent of those with acne and 11 per cent of those without). A similar lack of relation to the menses was also noted by Cunningham and Lunsford.³

Eighty girls with acne were questioned in greater detail and among them the apparent incidence of abnor-

the urine or blood indicate that there may be some association with the gonadal secretions, but the results of endocrine therapy of acne have not been satisfactory. The administration of thyroid substance, estrogen, androgen or the sex-stimulating principle of the pituitary gland may in selected cases result in considerable improvement, but there are many failures after the routine use of such preparations. There are obvious objections to giving active hormonal therapy to a group of adolescents having no gross evidence of endocrine disease; in particular the prolonged use of estrone or testosterone might easily have an undesirable inhibitory action on the pituitary gland. In order to avoid some of the objections to injection therapy and yet to give the estrogenic agents another trial, a series of patients was treated by use of a cream containing a modified estrogen. The cutaneous application of estrogen is known to be followed by a systemic effect and also by a local action on the epithelial structures.

A series of forty-nine girls with acne were treated by the external use of the dihydro form of estrogen. Improvement was noted in 72 per cent of these patients, a proportion which would suggest that this is a therapeutic method of value; but the validity of this conclusion is questioned after observation of similar improvement in 64 per cent of girls in a control series who used the same ointment base without estrogen. This lack of response to local estrogenic therapy and the relatively unsatisfactory results of estrogenic and androgenic injections are disappointing to one who seeks to link acne and the secretory organs.⁶

COMMENT

The purpose of this study was to search for clinical evidence relating acne and endocrine imbalance, an association suggested particularly by the age of onset and the course of acne. The microscopic pathology, the clinical appearance of the eruption and the results of treatment give little evidence to prove or disprove such a relationship. Chemical and biologic studies of the urine and blood show some variations in hormone content but do not prove that acne is an endocrine disease.

A number of observers have made statements which, if true, would be further evidence for associating the endocrine glands and acne. For example, it has been said that acne does not occur in persons with alopecia, a statement with which I cannot agree. Others have said that acne always disappears with marriage, but there are numerous exceptions to this rule. Riley⁷ stated that irregular sex practices possibly cause acne persisting after marriage.

Several serious attempts have been made to correlate acne and other clinical symptoms,⁸ but none of them have been very successful. Sallenbach-Keller established a relationship between the onset of acne and the appearance of the menses, and Cunningham's evidence suggests an association with enlargement of the thyroid gland. Numerous writers have commented on the incidence of irregular menses in about a third of girls having acne but have not shown that this rate is significantly higher than normal.

In my series of 3,119 girls the incidence of abnormal menses was not related to the presence or absence of

acne. Although girls with severe acne had a greater tendency to abnormality of menstruation, it is not unlikely that the incidence of abnormal menses is higher when associated with severe examples of any disease whether or not the disease is endocrine. Abnormal menses were twice as common among girls having a premenstrual flare-up.

The records of 4,235 university students did not show any significant association between acne and the weight or form of the body except that asthenic girls may perhaps be less likely to suffer from severe forms of acne. This is obviously not an observation on which extensive conclusions can be based.

Girls with acne were found to have lower metabolic rates than boys with the disease. Higher metabolic rates were recorded for both sexes when the eruption was extensive. These observations are probably significant but I am unable to explain them.

Study of the color and texture of the hair failed to indicate any association with acne.

Seborrhea, more severe involvement with acne, more extensive eruptions and a pustular tendency were observed more commonly in the boys, but these features have no evident association with endocrine disease.

SUMMARY

As a result of this review I am unable to point out any clinical evidence which might aid in establishing an etiologic relationship between acne and endocrine imbalance. There appears to be a relationship to abnormal thyroid function, but this is demonstrable only by changes in the basal metabolic rate and is not a clinical observation. In severe cases of acne there is some association with menstrual irregularity but in milder cases this association is not evident. With reference to acne of a mild or moderate degree, it is hardly possible to say more than that it accompanies the process of puberty and sexual maturation.

350 St. Peter Street.

ABSTRACT OF DISCUSSION

DR. J. G. HOPKINS, New York: Dr. Lynch's collecting and analyzing of this great body of data puts us all in his debt. We now have some facts to study and from these some of us may draw different conclusions. The outstanding thing seems the age incidence, 47 per cent in girls and 51 per cent in boys, wasn't it, in a group of the mental age of a college freshman? I suppose that would be a calendar age of about 18.

DR. LYNCH: The age was 19 in the males and females.

DR. HOPKINS: Well, at that age Bloch reported even higher percentages, which may be due to the different populations sampled or to a different interpretation of what are the lower limits of acne. Both reports lead to the conclusion that at that age the person with acne is the normal; the person without acne is the abnormal. Now the fact that it is in a sense a normal occurrence at the time of arrival at sexual maturity or shortly thereafter does not, of course, prove that it is of endocrine origin, but it seems to me strongly suggestive of an essential endocrine basis. In his data one other thing stood out confirming the general belief that an exacerbation, by which we probably mean a development of pustules, occurs quite regularly with the menstrual period. I think it is hard to dodge the implication that that means endocrine action. As to this we have more direct evidence in reported studies on excretion of estrogen in these patients. While the observations of Kurzrok and Rosenthal of a complete absence of excreted estrogen in the majority of acne patients have not been confirmed, I don't think they have been controverted and subsequent reports of similar studies have pointed somewhat in the same direction. These interesting data give us much to think about and analyze. I think it is possible to draw slightly different conclusions from those which Dr. Lynch presented.

6. The result of treatment of these patients is reported in greater detail in a brief paper (Arch. Dermat. & Syph., to be published). The material was provided by Dr. Gregory Stragnell, Schering Corporation, Bloomfield, N. J.

DR. R. L. SUTTON JR., Kansas City, Mo.: My interest in acne is the practitioner's problem of curing the patient. I offer a hypothesis about its etiology. Bloch wrote: "Only the comedo [first] phase of acne can be brought into direct relationship with endocrine processes. The second phase is characterized by an inflammatory process on the basis of infection. It may follow the first, but this is not inevitable." If the inflammatory phase were the result of infection with *Corynebacterium acnes*, said to be present invariably, the second phase ought to be inevitable. It is not, and I believe that the saprophyte has been unjustly maligned. Bloch assumed that inflammation implies infection, overlooking the fact that the inflammatory phase of acne is foreign body reaction to lipid. It is a tuberculoid reaction which has caused pathologists to confuse acne with tuberculosis. It results from the introduction of lipid into mesodermal tissues and has nothing to do with parasitism. It may result from bruising a comedo or from injecting lipoidal material into the skin as Sabin injected fractions of *Mycobacterium tuberculosis*. Hass injected fatty acids of olive oil and cod liver oil and learned that less saturated fatty acids are more irritating. A comedo once formed, like a xanthomatous deposit, cannot be resorbed easily. Its resorption requires an inflammatory lesion. Phagocytism perhaps is instigated by discontinuity of the epithelial barrier separating comedo from mesoderm. Trauma can cause the breach. Foreign body reaction may take place shallow or deep, and phagocytes may attack either solid, well saturated lipid or liquid, less saturated material. The clinical picture varies with the location and severity of the inflammatory process. Acne vulgaris I define as the disease which consists of tuberculoid inflammatory reaction to sebum which is abnormal because of improper metabolism of lipid. Acne is a kind of pustular lipoidosis. In contrast with primarily mesodermal lipoidoses (xanthomatoses), acne is primarily epidermal lipoidosis with secondary inflammation. Acne depends on excessive ingestion of oil: milk, cream, ice cream and butter are chief offenders; so are pork and cod liver oil. Girls get acne when they try to gain weight by drinking milk and taking cod liver oil. Acne depends on hormonal influences through the interrelationship of thyroid function and lipid metabolism. Lipemia designates hypothyroidism more dependably, Hurxthal proved, than basal metabolic rate determinations. Vitamin A is concerned, for its excess counteracts the patient's autogenous supply of thyroxine. When one's intake of lipid and vitamin A exceeds one's ability to metabolize them, one may develop deposits in the sebaceous glands, to which may develop inflammatory reactions. Treatment based on this etiologic interpretation works in practice.

DR. J. D. FARRIS, Richmond, Ky.: Dr. Lynch's paper is particularly interesting to me because as a college physician in a state college I deal with this age group of young people and the sexes are about equally divided. I wish to corroborate the many points that he brought out in this particular subject and wish to state that I have found many of the same points to be true in the examinations of several thousand boys and girls over the last few years. He mentioned using estrogenic substance in the paste or ointment and I wonder what his experience has been in using it hypodermically, or some product such as antuitrin-S. I myself have had some rather good results in these cases, quite satisfactory to the young people, by injections of these substances.

DR. FRANCIS W. LYNCH, St. Paul: I have no report on the results of treatment by the injection of estrogenic agents because I have not felt justified in administering such treatment as a routine to these students. Dr. B. A. Watson of the student health service has been in communication with Dr. Sutton and we have been stimulated by Dr. Sutton's theory as to the pathogenesis of acne. A boy with a severe, chronic, papular and pustular acne involving the face and trunk was placed, on a measured and weighed diet for two months, part of the time with low, normal and high fat content. With these diets we failed to note any influence on the blood cholesterol level or any significant association with the course of the eruption. At one period the eruption improved noticeably while the diet was high in fat content. This one case is reported not as conclusive evidence but merely as a single experiment. I hope that Dr. Sutton will report on a series of patients treated according to his suggestions. Dr. D. W. Cowan at the health service has recently

performed vitamin C determinations in the blood of several hundred students. In reviewing the results of these studies, he failed to observe any association between the vitamin C level and the presence or absence of acne. I did not acquire this information in time to include it in my report but thought that it might be of interest to the members of the section, particularly because of the relationship between vitamin C and the adrenal glands and the possibility that the amount of vitamin C in the blood may be some indication of the functional activity of the adrenal glands. I agree with Dr. Hopkins that there are many reasons for assuming a relationship between acne and the endocrine system. I should have made clear that the conclusions I presented today are based only on the studies and material of this report and are to be regarded as only one portion of the evidence which must be reviewed in making a final judgment of the cause of acne.

SMALLPOX VACCINATION OF INFANTS

REVACCINATIONS AFTER TWO TO THREE YEARS
IN CHILDREN PRIMARILY VACCINATED WITH
CULTURE VIRUS (RIVERS), COMPARED
WITH THOSE PRIMARILY VAC-
CINATED WITH CALF
LYMPH VIRUS

HARRY H. DONNALLY, M.D.

WASHINGTON, D. C.

Revaccinations of children from 2 to 3 years of age, among those who had been vaccinated¹ in 1935 and 1936 in the newborn nurseries of Gallinger Municipal Hospital within a few days of their birth, were done in June and July 1938. The total number of these revaccinated children followed through to involution of the skin reactions numbered seventy, almost exactly half of whom (thirty-six) had had successful primary takes at birth with culture vaccine virus (Rivers)

Fig. 1.—Primary vaccination when child was 3 hours old. Culture virus (Rivers) M60, intradermally; unsuccessful. June 22, 1938; no scar. Revaccination when child was 2 years 8 months old. New York calf lymph; thirty needle pressures cutaneously. Early appearance of skin reaction: Present within twenty hours. Rapidity of vaccine cycle: Not increased; eighth day at or near peak. Intensity of skin reaction: Large take. Estimate of immunity: None. A, third day; B, fifth day; C, eighth day.

inoculated intradermally, and the other half (thirty-four) had had successful takes at birth with calf lymph virus, two thirds (twenty-three) by the intradermal

From the Pediatric Department, George Washington University School of Medicine, and the Allergy Clinic of Children's Hospital. Read before the Section on Pediatrics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939. Made possible in part by a grant from the National Research Council and a grant from Lederle Laboratories, Inc., Pearl River, N. Y. 1. Donnally, H. H.; Nicholson, M. M.; Anderson, W. S., and Grosvenor, M. H.: Intradermal Vaccination of Newborn with Culture Virus (Rivers) Compared with Intradermal Vaccination with Diluted Calf Lymph in Over 1,000 Babies, to be published.

method and the other third (eleven) by the cutaneous method (Leake's² multiple pressures). The skin reactions were essentially the same whether the intradermal vaccination had been performed with culture virus (Rivers) or diluted calf lymph virus (New York Bureau of Laboratories) but tended to appear earlier with calf lymph. Each of these viruses could give marked variation in intensity of skin reaction in different babies.

The scars of these primary takes were readily found because newborn infants were vaccinated uniformly on the outside of the left leg just below the head of the fibula. In the culture virus takes the scars were absent in 35.1 per cent and not over 5 mm. in diameter in 32.4 per cent, whereas in the primary calf lymph takes there were scars in excess of 10 mm. in diameter in 62 per cent, and no visible scar in one child (3 per cent). Intradermal inoculations of diluted calf lymph virus, 1 part in 100 of 0.85 per cent sodium chloride solution gave as a rule a smaller skin reaction and a smaller scar than the cutaneous multiple pressure. The percentage of successes was 93 per cent, the same whether the calf lymph was inoculated intradermally or cutaneously (table 1).

TABLE 1.—Size of Primary Scars

Virus Used in Primary Vaccination	Total Cases (71)	No Record of Scar	No Visible Scar	2 Mm. or Less	2 Plus 5 Mm.	5 Plus 10 Mm.	10 Plus 20 Mm.	Over 20 Mm.
Culture virus (Rivers) intradermal.....	37	3 (8.1%)	13 (35.1%)	6 (16.2%)	6 (16.2%)	6 (16.2%)	3 (8.1%)	0
Calf lymph virus	34	0	1 (3%)	0	4 (11.8%)	8 (23.5%)	11 (32.4%)	10 (29.4%)
Intradermal....	23	1	1	0	4	8	10	0
Cutaneous.....	11	0	0	0	0	0	1	10

Sizes of scars resulting from successful intradermal vaccinations with culture virus (Rivers) at birth, after two to three years: no scars in 35 per cent, and in the remainder small scars. Calf lymph virus scars resulting from successful intradermal or cutaneous vaccinations at birth, showed no scar in 3 per cent, and scars over 10 mm. in diameter in 62 per cent.

In a former publication³ in discussing the duration^{3a} of immunity to vaccination and to smallpox, the following statement occurs summarizing facts⁴ which relate to the subject: "Skin reaction to revaccination indicates

2. Leake, J. P.: Questions and Answers on Smallpox and Vaccination, Pub. Health Rep. 42: 221 (Jan. 28) 1927.
3. Donnally, H. H., and Nicholson, M. M.: A Study of Vaccination in Five Hundred Newborn Infants, J. A. M. A 103: 1269-1275 (Oct. 27) 1934.
3a. Rivers, Ward and Baird (Amount and Duration of Immunity Induced by Intradermal Inoculation of Cultured Vaccine Virus, J. Exper. Med. 69: 857 [June] 1939) state: "It is known that infants shortly after birth (Donnally, H. H., and Nicholson, Margaret M.: A Study of Vaccination in 500 Newborn Infants, J. A. M. A. 103: 1269 [Oct. 27] 1934) are somewhat resistant to infection with vaccine virus. Furthermore, it has been demonstrated (Donnally and Nicholson, loc. cit.) that such infants after a successful vaccination rapidly lose their immunity, many being fully susceptible a year later." Our conclusion was contrary to this. The completely immune are two and one-fourth times the number of nonimmune, as reported in 1934 for revaccinations of fifty-two infants from thirteen to sixteen months after successful vaccination at birth. Rivers, Ward and Baird state also that reports in the literature concerning the duration of immunity in children to vaccine virus are conflicting. This we have found to be true. Sergeant and Trens (De la perte d'immunité vaccinale, Bull. Acad. de méd., Paris 107: 625, 1932) state that the anti-smallpox vaccine prepared at the Institut Pasteur d'Algérie, which gives 100 per cent positive results with primary vaccinations on the newborn, gave the results presented below on persons previously successfully vaccinated and followed:

Age	Revaccinations	Reactions of the Primary Type	Percent of Reactions of the Primary Type
From 2 to 10 years	1,947	1,243	63%
From 11 to 20 years	946	539	56%

The detailed tables of these writers show that the proportion of successful revaccinations does not vary significantly from childhood to the age of 20 years.

4. Pirquet, Clemens: Klinische Studien über Vakzination und vakzinalle Allergie, Leipzig and Vienna, 1907.

the individual's degree of protection; in the early months following first vaccination he may be completely insusceptible; he may show varying alterations in skin reactivity, particularly after the first vaccination, the early appearance of these, the rapidity of the cycle, and the intensity of the skin reaction being indications of

TABLE 2.—Early Appearance of Skin Reactions

his state of immunity. The strength of smallpox protection is closely related to that of skin protection to revaccination; complete immunity or insusceptibility to revaccination is a temporary state." In each revaccination of the seventy children, a record was made when possible with regard to the early appearance, the rapidity of the vaccinal cycle and the intensity of the skin reaction. With these data an attempt was made to make an appraisal of the degree of immunity present in each of the children.

A control group of twelve children of similar age who had never been successfully vaccinated before were vaccinated in the same manner, at the same time and with the same batch of calf lymph virus.

VIRUS USED AND METHOD OF REVACCINATION

A fresh lot of calf lymph virus was obtained from the Bureau of Laboratories of the Department of Health of New York when we were ready to start the revaccinations. This was carefully protected in transit and while in our hands by keeping at low temperatures until actually used. Both groups, (1) the children

TABLE 3.—Rapidity of Vaccinal Cycle

Virus Used in Primary Vaccination	Total Cases (71)	Vaccinal Cycle Accelerated	Vaccinal Cycle Not Accelerated	Unknown
Culture virus (Rivers) intradermal....	37	17 (46%)	19 (51.4%)	1 (2.7%)
Calf lymph virus.....	34	29 (85.3%)	5 (14.7%)	0
Intradermal.....	23	19	4	
Cutaneous.....	11	10	1	

Children primarily successfully vaccinated intradermally at birth with culture virus (Rivers) showed on revaccination with calf lymph cutaneously after two to three years no acceleration of the vaccinal cycle in nineteen (51.4 per cent) of thirty-six revaccinations. Children primarily successfully vaccinated intradermally or cutaneously at birth with calf lymph virus showed on revaccination with calf lymph virus cutaneously after two to three years acceleration of the vaccinal cycle in twenty-nine (85.3 per cent) of thirty-four children.

primarily vaccinated with culture virus (Rivers) and (2) those primarily vaccinated with calf lymph virus (New York Bureau of Laboratories), either by multiple pressure and rubbing or by intradermal inoculation of diluted calf lymph, were revaccinated vigorously by thirty multiple pressures with the needle through

a drop of calf lymph on the skin, followed in each instance by moderate rubbing with the shaft of the needle and with the identical batch of virus. The plan was to use a "hot virus" and a severe technic of vaccination to insure uniformly a high percentage of takes. Thirty-eight revaccinated children were admitted

and the eighth day after and occasionally later. Records of the sizes of the papilla, redness, crusting, areola and adenopathy were also made.

EARLY APPEARANCE OF SKIN REACTIONS

In every instance among the children previously inoculated successfully with culture virus or with calf lymph virus, the skin reaction (table 2) appeared by

TABLE 5.—*Estimate of Immunity as Disclosed by Severe Cutaneous Revaccination*
(New York Bureau of Laboratories, calf lymph, thirty needle pressures cutaneously)

Virus Used in Primary Vaccination	No. of Cases (70)	Slight or None	Fair	Good	Immune Reaction
Culture virus (Rivers) intradermal.....	36	29 (80.5%)	5 (14%)	2 (5.5%)	0
Calf lymph virus.....	34	7 (20.6%)	2 (6%)	14 (41.2%)	11 (32.3%)
Intradermal.....	23	6	2	10	5
Cutaneous.....	11	1	0	4	6

Estimate of immunity: Among thirty-six children successfully vaccinated intradermally at birth with culture virus (Rivers), revaccination after two to three years with calf lymph virus cutaneously showed twenty-nine (80.5 per cent) to have apparently slight or no immunity and five (14 per cent) apparently to have fair and two (5.5 per cent) good immunity. Among thirty-four children successfully vaccinated intradermally or cutaneously at birth with calf lymph virus, revaccination after two to three years with calf lymph virus cutaneously showed seven (20.6 per cent) to have apparently slight or no immunity and 73.5 per cent apparently to have good immunity.

Fig. 2.—Primary vaccination when child was 23 hours old. Culture virus (Rivers) M54, intradermally; successful. Culture mediums unseeded as control. A, second day; B, third day; C, fourth day; D, fifth day; E, sixth day; F, seventh day; G, eighth day; H, ninth day.

immediately to the Children's Hospital, Washington, D. C., for observation during five days. Of the children admitted to the hospital, eighteen had been primarily inoculated successfully with culture virus,

the following day. In one child, unsuccessfully vaccinated at birth with culture virus, there was an identical early appearance of the skin reaction. The incubation period in nineteen consecutive newborn vaccinations were as follows: two days, four babies; three days, eleven babies; four days, four babies. This is an unsatisfactory control group because in the previous study³ it was emphasized that newborn infants were

TABLE 4.—*Intensity of Skin Reactions*

Virus Used in Primary Vaccination	No. of Cases (71)	Greater Than Primary	Similar to Primary	Less Than Primary	Unknown
Culture virus (Rivers) intradermal.....	37	34 (92%)	2 (5.4%)	0	1 (2.7%)
Calf lymph virus.....	34	5 (14.7%)	2 (6%)	27 (79.4%)	0
Intradermal.....	23	5	2	16	0
Cutaneous.....	11	0	0	11	0

Intensity of skin reaction on revaccination: Thirty-seven children successfully vaccinated at birth with culture virus (Rivers) intradermally showed on revaccination with calf lymph virus cutaneously greater intensity of skin reaction in thirty-four (92 per cent). Thirty-four children successfully vaccinated at birth with calf lymph virus intradermally or cutaneously showed on revaccination with calf lymph virus cutaneously greater intensity of skin reaction in five (14.7 per cent) and less intensity of skin reaction in twenty-seven (79.4 per cent).

nineteen successfully with calf lymph virus, and one unsuccessfully with culture virus. Their temperatures were taken regularly. The skin reaction was observed and recorded from three to five hours after inoculation, from eighteen to twenty hours after and from twenty-eight to thirty hours after. They were observed daily for the next three days during their stay in the Children's Hospital. They were then discharged as inpatients to report in the outpatient department until involution of the skin reaction. Photographs of the skin reactions were made in each child on the third day (forty-eight hours) after inoculation, the fifth day

Fig. 3 (same child as in figure 2).—Primary vaccination when child was 23 hours old. Culture virus (Rivers) M54, intradermally; successful. June 22, 1938, size of sear 12 by 10 mm. slightly depressed. Revaccination when child was 2½ years old; thirty needle pressures cutaneously. Early appearance of skin reaction: Unknown. Rapidity of vaccinal cycle: Increased; eighth day involuting. Intensity of skin reaction: Large later, greater than primary. Estimate of immunity: Slight, if any. A, third day; B, eighth day.

successfully vaccinated somewhat less readily than children of 3 years. It is a common observation, however, among children primarily vaccinated at 3 years, that the skin reaction appears first on the third day or subsequently. No group of children of 3 years of age

vaccinated for the first time is available, followed as soon and as frequently after primary vaccination as necessary to use for controls. One may safely conclude that the early appearance of the skin reactions in 100 per cent of the thirty-eight children admitted to the Children's Hospital for an observation period of five

per cent (thirty-four children), similar to the primary in 5.4 per cent (two children) and unknown in one child (2.7 per cent) whose mother took him out of the city, and less than primary in no case. Among the children primarily vaccinated at birth with calf lymph virus either intradermally or cutaneously, the intensity of the skin reactions on revaccination was greater than the primary in 14.7 per cent (five children), similar to the primary in 6 per cent (two children) and less than the primary in 79.4 per cent (twenty-seven children).

Fig. 4.—Primary vaccination when child was 10 hours old. Culture virus (Rivers) M52, intradermally; lymph, thirty pressures cutaneously. Revaccination when child was 234 years old. New York calf lymph. June 29, 1938, no visible scar. Early appearance of skin reaction: Present within twenty hours. Rapidity of vaccinal cycle: Not increased; eighth day at or near peak. Intensity of skin reaction: Very large take; greater than primary. Estimate of immunity: None. A, fifth day; B, eighth day; C, fifteenth day; D, seventeenth day.

ESTIMATE OF IMMUNITY

An estimate of immunity (table 5) in each of the children revaccinated was made in four groups: (1) slight or none, (2) fair, (3) good and (4) immune reaction. In the slight or no immunity group were placed those children who on revaccination gave skin reactions which approximated the intensity of the

primary vaccinations among the twelve children who served as controls (fig. 1). Those primarily vaccinated with culture virus (fig. 2) were found to have slight or no immunity, as described, in 80.5 per cent (twenty-nine children) (figs. 3 and 4). In the calf lymph primary vaccinations there was slight or no immunity in 20.6 per cent (seven children). The children grouped as having "fair" immunity were those who showed beginning involution on the eighth day after revaccination. Among those primarily vaccinated with culture virus there were 14 per cent (five children) showing "fair" immunity, and among those primarily

RAPIDITY OF VACCINAL CYCLE

By following the skin reactions to vaccinia virus inoculations, through to involution, the rapidity of the vaccinal cycle (table 3) was observed. It was regarded as an accelerated cycle when involution made its appearance on or before the eighth day after revaccination. In primary vaccinal cycles the peak of the reaction may rarely sooner. Among culture virus cases in thirty-seven revaccinations the cycle was accelerated in 46 per cent (seventeen children) and not accelerated in 51.4 per cent (nineteen children). Among those primarily vaccinated with calf lymph virus the vaccinal cycle was accelerated in 85.3 per cent (twenty-nine children) and not accelerated in 14.7 per cent (five children).

INTENSITY OF SKIN REACTIONS

The intensity of skin reactions (table 4) to vaccinia virus seems to be a better index of probable immunity than both early appearance of skin reaction and accelerated vaccinal cycle. In recording the measurements and intensity of skin reactions in the revaccinations studied, observations were made and compared with the protocol of the skin reaction in the primary take which occurred shortly after birth. These reactions fell into three groups, in which the revaccination was greater than the primary, similar to the primary, and less than the primary. The intensity of skin reactions to revaccination as described in children primarily with culture virus was similar after than the primary in 92

Fig. 5.—Primary vaccination when child was 32 hours old. New York calf lymph, intradermally. Revaccination when child was 1 year 11 months old. Thirty needle pressures cutaneously. Early appearance of skin reaction: Present within twenty-eight hours. Rapidity of vaccinal cycle: Increased; fifth day at peak; eighth day well involuted. Intensity of skin reaction: Less than that of primary vaccination. Estimate of immunity: Immune reaction. A, third day; B, fifth day; C, eighth day.

vaccinated with calf lymph virus "fair" immunity was found in 6 per cent (two children). "Good" immunity was estimated for those children who on revaccination had accelerated vaccinal cycles, considerably less intense skin reactions than the control group and than their

Dean Lewis⁹ stated his experience, which is that of many surgeons.

The changes occurring in a nerve fiber following a constriction and its removal, attended by a rapid return of function, have not been established. Clinical experience would seem to indicate that the conducting power of a nerve may be totally suspended for months and that within a few days following removal of the constricting band motor function may return. I have seen return of function in the extensors of the forearm within ten days following the removal of a very delicate constricting band which reduced the diameter of the musculospiral nerve by one half. The paralysis had been present for six months. Delicate scar tissue about a nerve in which there are no evidences of intraneural scar may cause the same suspension of function.

There may thus be changes in the muscles, fasciae or sheaths about nerve trunks which later may constrict them, even though they have escaped direct effects of the compression.

A report of five clinical cases follows.

REPORT OF CASES

CASE 1.—*Stumble while carrying heavy object. Sudden pain in leg and appearance of weakness of peroneal group of muscles in two hours. Partial reaction of degeneration.*

Stanley B., a white man aged 48, a truck driver, whose family history was irrelevant, was well until March 5, 1937, when he had an accident. He had had two previous accidents, in one of which his left leg was injured and in the other his back was strained, but neither seems to have any bearing on the present problem.

On March 5 at about 4:30 p. m., while he was carrying one end of a showcase through a doorway, he stumbled with his right foot and immediately felt a sharp pain in the leg (peroneal region) but continued with his work. His foot began to tingle but he drove his truck back to his place of business, reaching it at about 5:30 p. m. He went to his home and had to wait a short time for his supper; thus one and one-half to two hours had elapsed from the time of the accident. On arising to walk to his dining room he noticed that he could not raise his toes from the floor. He massaged the foot and leg with liniment and soaked the foot in a solution of magnesium sulfate.

On the following day he was unable to work because he could not tell when driving his car whether his foot was properly pressing on the brake or accelerator, and when I examined him eighteen days later he still had foot drop.

Examination showed the patient to be well nourished and in good general physical health except that he had considerable sclerosis of the arteries. His blood pressure was 140 systolic and 106 diastolic. The osseous system was normal. There was, as stated, foot drop on the right, and the right leg at the calf was slightly smaller in circumference than the left (the peroneal group a little smaller). Extension of the toes was weak but not so weak as flexion of the ankle. There was hypesthesia in the area of skin supplied by the common peroneal nerve. Otherwise results of the neurologic examination were entirely negative.

Electrical reactions showed loss of faradic irritability in the right peroneal group of muscles, but the cathodal closing was greater than the anodal closing contraction. There was thus a partial reaction of degeneration.

CASE 2.—*Patient fell 15 feet, alighting on his feet. Fracture of right os calcis but foot drop on the left. Examination after eleven months showed complete reaction of degeneration of common peroneal nerve.*

James W. T., a white man aged 52, a mechanic, was well until March 30, 1934, when, while working at his usual occupation of moving a safe, he lost his balance. Realizing that he was about to fall he leaped clear of obstructions and landed

on his feet on concrete 15 feet below. He had immediate severe pain in both feet and was unable to stand.

Taken to the hospital, he was examined by surgeons and the right os calcis was found fractured. The left foot was discolored and badly bruised but the bones were not fractured. The patient was hospitalized for only five days, and when he was allowed to go home foot drop was discovered on the left. He was confined to his home for five weeks and then he got about on crutches, resuming work in October.

When I saw him on Feb. 18, 1935, there was essentially nothing wrong with the patient except for foot drop on the left. There was no arteriosclerosis or other physical abnormality, and no predisposing cause for the foot drop could be found, but that condition was complete. The toes could not be raised. An area of anesthesia was found corresponding to the distribution of the common peroneal nerve. Electrical reactions showed complete absence of faradic and galvanic irritability, and there was atrophy of the peroneal group of muscles.

CASE 3.—*Healthy man suffered fall astride of plank and reached forward and upward with right hand to grasp support but failed to reach it. Usual signs of urethral injury but also paralysis of right serratus anterior muscle. Partial reaction of degeneration of long thoracic nerve.*

Isidor L., a man aged 37, Jewish, a laborer, with an irrelevant family and past personal history, was well and working at his usual occupation until March 10, 1930, when he suffered an accident. He was walking along a plank entering a new dwelling before an entrance had been constructed when he lost his balance and fell astride the plank. He reached forcefully forward and upward for support, which he failed to attain. However, he held to the plank with his legs and did not fall off it. He suffered for some hours with pain in his shoulder.

He was taken to a hospital because of the local injury and hematuria and remained there for three weeks. Weakness of the right shoulder appeared after some days, but as he remained in bed this gave him no particular trouble and he did not realize its seriousness. When he was discharged to return to work he was unable to do so.

When I saw him on May 21 he had been studied by several surgeons and the Wassermann reaction and roentgenograms of the shoulder had been examined, but no light had been thrown on the case from those points of view. Dr. Wallace Dodge believed the patient had a neuritis of the long thoracic nerve and referred him for possible reaction of degeneration.

There were the classic features of paralysis of the serratus anterior muscle on the right. At rest there was hardly any deformity, but when the arms were extended the angle of the right scapula projected far backward and the patient was unable to raise the arm well above the shoulder. The paralysis was so complete that one could with ease insert one's fingers between the scapula and the dorsal muscles and take hold of the scapula. This facilitated the test for reaction of degeneration because one could feel the contraction of the serratus anterior muscle when the nerve was stimulated. Other muscles were not involved.

The blood pressure was found to be 126 systolic and 85 diastolic. The pulse rate was 72 per minute and the arteries were in good condition. The heart and lungs were normal; in short, there was nothing of moment in the general physical examination, and the neurologic examination gave only the evidence incident to the paralysis of the serratus anterior muscle on the right. Some difficulty was encountered in attempting to stimulate the long thoracic nerve alone with the electric current. Because of a fairly good panniculus adiposus and good musculature in general the current tended to spread. However, after considerable effort success was obtained and stimulation with a small pole gave a contraction in the serratus anterior muscle alone. The cathodal closing contraction was found to be greater than the anodal closing, but no irritability at all to the faradic current was found.

At that time I was not acquainted with paralyzes occurring from such accidents and was inclined to believe that an independent neuritis had developed. For this reason the patient

⁹ Lewis, Dean: Some Peripheral Nerve Problems, Boston M. & S. J. 188: 975 (June 21) 1923.

sought another physician, who diagnosed, without knowledge of the details just described, a separation of the muscle from the scapula; he surgically fixed the scapula to the posterior thoracic wall.

CASE 4.—Sudden thrust of right arm upward during impending fall. Pain in region of right shoulder still present one month later. Gradual appearance of atrophy of right trapezius, spinati and rhomboid muscles. Diminished faradic irritability of right dorsalis scapular nerve.

Herbert R., a white man aged 55, a laborer, had had typhoid in 1902 and an appendectomy in 1924. He was referred to me on Aug. 29, 1936, because of pain in the region of the right shoulder dating from an accident July 21 of the same year. He gave a history of being perfectly well and working as usual packing cases in the warehouse of a soap factory when his left foot slipped forward. He threw his right arm upward over his head to balance himself and immediately felt a very sharp pain in the right shoulder joint. He became nauseated and vomited and was unable to continue work.

He was treated at his home for four days with massage and liniment before he returned to work. When he did return he continued to have the pain, which was worse at night. When the pain was severe he obtained some relief by placing his arm over his head. He was referred five weeks after the accident because of lack of improvement.

The patient was well nourished and in good general physical condition. The blood pressure was 164 systolic and 90 diastolic. The radial and brachial arteries were palpable but not materially sclerosed. The teeth were in poor condition. The essential changes were referable to the muscles of the right shoulder region. There was atrophy of the infraspinatus and supraspinatus, rhomboid and trapezius muscles, all on the right side only. There was a little winging of the right scapula, apparently from the weakness of the rhomboids and the trapezius. There was otherwise essentially no pathologic feature.

Electrical reactions showed reduction of faradic irritability of the right dorsal scapular nerve as compared with the left. The relations of the two types of galvanic reactions were normal.

CASE 5.—Slipping of foot from rung of ladder to ground. Pain, progressive paresthesia, followed by foot drop after fourteen hours, which increased for two days. Splinting of foot. Gradual recovery.

P. M. M., a white man aged 41, suffering from chronic but well compensated valvular disease of the heart, was referred by the state industrial accident commission because of dropping of the left foot. Except for "heart trouble" resulting from scarlet fever at the age of 8, tonsillitis at one time early in life and mild influenza during the World War, he had always been well and able to carry on his work as a carpenter.

On Nov. 22, 1938, he had a minor accident affecting the left foot. He was about to ascend a ladder with 30 pounds of shingles on his left shoulder and had placed his left foot on the first rung, when he turned at the sound of an automobile horn behind him. The distraction caused his foot to slip off the rung and strike the ground with some force, so that he immediately felt a sharp pain across the ball of the foot. However, he climbed up the ladder and continued with his work as usual for the one and a half hours of the day still remaining. The foot continued to pain him and swelling gradually appeared along the dorsal region of the transverse arch.

When the day's work was done he drove his own car home, and he slept as usual that night. When he arose the next morning he still had some pain in the ball of the foot, and numbness had appeared over the dorsum of the great toe and over the adjacent portion of the foot. The swelling of the dorsum of the foot had increased. As the patient attempted to walk he discovered that the toes of the injured foot tended to drag. Because of shortage of building materials there was no work for him to do on that day, so he remained at home and nursed the foot with hot fomentations and massage.

The second day following the accident was a holiday so he again remained at home. The foot drop was then found to

be complete and the numbness had extended half-way up the anterior surface of the leg. On the third day, as he was unable to carry on his work, which was then available, he consulted a physician, who found the foot drop complete and applied a cast. This was removed on the following day and a splint substituted to prevent stretching of the paralyzed muscles. Physical therapy was started, and the patient remained at home.

I saw the patient thirteen days after the injury. He stated that his foot was much improved, so that he could raise his toes slightly off the floor. He was a heavily built man weighing 218 pounds (99 Kg.) and was 70¾ inches (177 cm.) tall. Aside from a little lateral enlargement of the heart and a booming first sound, plus six badly infected teeth with surrounding pyorrhea, the left foot was the only element worthy of note in the physical examination. The patient was able to stand on the ball of either foot separately but was unable to raise the toes of the left foot when attempting to stand on his heels. There was hypesthesia to touch and pin prick on the dorsum of the foot and ankle, above which it gradually shaded off to normal. There was neither pain nor swelling in the tissues of the foot. Electrical reactions showed a slight diminution to faradic stimulation in producing dorsiflexion of the toes and foot. Otherwise conditions were normal.

A diagnosis was made of compression neuritis of the left common peroneal nerve, due to muscular action, in the stage of recovery.

This case seems unusually clear as one of the type here presented in that the paralysis progressed for two days after the injury in spite of rest. The paralysis seemed to begin fourteen hours after the accident and progress to completion in another twenty-four hours.

COMMENT

When it is recognized that muscular contractions, even a single forceful or unusual contraction, can thus after a latent period of hours or weeks give rise to functional paralysis of a nerve, there is danger of ascribing any obscure paralysis to some muscular action, especially if minute inquiry is made in every case. I would postulate that in a given case before paralysis is ascribed to muscular action certain conditions must be present: 1. There must have been some sort of sensory discomfort in the affected area at the time of the accident. 2. There must have been a recurrence or continuation of the discomfort for some hours or days. 3. The paralyzed nerve must be anatomically so situated that the muscles involved in the unusual strain compressed it in the act considered etiologic. 4. The paralysis must have appeared within, say, two months of the strain.

SUMMARY AND CONCLUSIONS

Attention is called to paralysis of peripheral nerves resulting from a single unusual muscular contraction and also to the delayed appearance of the paralysis.

As such paralysis may result from such action as a stumble, a sudden reaching forward or a sudden thrust of the hand upward for the purpose of regaining one's balance, the etiology is easily overlooked and in industrial work the industrial nature is often not conceded.

It is quite probable that more than one type of etiology may be concerned in such cases, e. g., intoxication, general anesthesia or chilling, but the muscular action with resultant contusion of the nerve is the exciting cause.

To avoid the danger of ascribing any obscure paralysis of a nerve to hypothetical muscular action I postulate that for a given case to be valid as belonging to this group there must have been (1) some sort of sensory discomfort in the affected area at the time of the injury, (2) continuance or recurrence of the

discomfort for hours or days, (3) possibility of compression of the affected nerve by the muscular contraction assumed responsible, and (4) appearance of paralysis within, say, two months of the strain.

727 West Seventh Street.

ABSTRACT OF DISCUSSION

DR. L. J. POLLOCK, Chicago: Lesions of the peripheral nerves are rare in civil life as compared with those that we saw in the war, and lesions of the peripheral nerves that occur as a result of indirect trauma are still rarer, and those that occur some time after trauma are rare indeed. One of the causes of a lesion of a peripheral nerve is a sudden, strong contraction of a muscle. Such a contraction could be the result of stretching such as would occur if you were falling off a ladder and you suddenly reached for a rung. Even if you do not grasp the rung of the ladder, you have produced a stretching. Another type is that which is produced by dislocation of a nerve, which might occur in an ulnar nerve resting in a rather shallow groove of the olecranon, where a contraction of the triceps might produce dislocation of the ulnar nerve, or you may produce a compression against a sharp edge of a muscle, just as Dr. Nielsen reported where the long thoracic nerve was compressed by the scalenus muscle, or at times the pronator teres may be compressed against the median nerve. If a nerve is injured by compression or by stretching or contusion, the effect on the nerve is immediate. If you ligate a nerve or if you bruise a nerve there is an immediate loss of function of that nerve of varying degree; therefore I think that in these instances of indirect trauma to nerves in which the symptoms occur some time after the injury we must consider the possibility of some other intermediate action whatever it might be. Among them are hemorrhages. There may be some inflammatory reaction of tissue adjacent to the nerve. Finally, one must give thought to the hypothetical consideration of what are known as the instances of traumatic mononeuritis, in which case they usually occur after some time, the bridging period of course also being held to some hypothetical reasonable duration where, under the condition of cachexia, chronic infection, chronic alcoholism or diabetes, a nerve that is what we would ordinarily consider mildly injured might then become the site of a mononeuritis. I am dubious as to the occurrence of such a condition. There is another circumstance that is apparent from these cases. The first patient noted a foot drop one and one-half hours after injury. The second patient landed on his feet and fractured the os calcis of one leg. He was put to bed, I take it, and on the fifth day it was noted that he had a foot drop on the left side. I have had that experience numbers of times, but does it mean that the foot drop occurred on the fifth day, and I should like to know whether they actually in examining the patient said that the foot drop was not present on the first day. A patient may come to us and have noted, for example, that he had a marked atrophy and the atrophy was progressive but the paralysis was immediate and perhaps not noted. I would conclude from this study that this is a rare group of cases to which our attention should be called, but we should be careful in evaluating the interval between the time of injury and the actual onset of loss of function and not the time when it is noted by the patient or some one else that some loss of function has occurred.

DR. R. B. RANEY, Los Angeles: From a surgical point of view, the conditions seen at operation in cases of nerve injury are almost too well known to be worthy of mention. However, cases are occasionally seen in which the paralysis appears later and extreme changes in the structure are observed at operation. I have had the opportunity of seeing only one such case, and changes had occurred not only in the overlying muscle but also in the nerve roots. This was the case of a 20 year old girl who had suffered an injury to the right brachial plexus. In attempting to avoid injury to her face from a breaking windshield during the automobile accident she turned her head sharply to the right, and the sudden stop of the car snapped her neck. She suffered at the time pain in the shoulder, arm and hand. There was some numbness and local tenderness, which largely disappeared in a few weeks. As far as neurologic signs following the injury were concerned, they were not definitely established since a neurologic examination had not been done. About

five weeks after the injury, pain and impaired motor function of the affected arm reappeared. Examination several months later showed involvement of almost the entire brachial plexus; impaired sensation and motor weakness were striking. Exploration revealed the scalenus anticus muscle largely replaced by fibrous tissue, adherent to the roots of the plexus. The scalenus anticus muscle was removed, showing the roots of the plexus extremely flattened. Recovery of function was remarkable but not complete. This case illustrates the profound changes in perineural structures and the delayed paralysis that can occur from a single muscular contraction with, of course in this case, other factors playing a part. Therefore it is not only conceivable but reasonable to assume that less severe muscular contractions can cause local injury to the perineural structures. Finally, secondary injury to the nerves themselves by contraction of fibrous tissue seems decidedly reasonable.

DR. PERCIVAL BAILEY, Chicago: I should like to ask Dr. Nielsen whether he had a reason for choosing two months as the upper limit or whether he was merely guided by the principle that the longer the time elapsed the less probable would be the causal association and thought merely that after two months it probably would be too slight to consider.

DR. J. M. NIELSEN, Los Angeles: As to the onset of the paralysis, I cannot say because I did not see the patient until some time afterward, but the records of the hospital in which the patient was placed gave the usual results of physical examination as made by the physician at the time and the usual visits without any mention of any paralysis. As to Dr. Bailey's question, I am guided by the improbability of things developing later, and I have tried to state the reasons for this more accurately in the paper. I have taken the attitude that something should be evident within two months. Weakness may develop as it did in some cases and continue to develop for many months, but there should be some indication before the end of the two months.

THE USE OF COLLOIDAL CALOMEL OINTMENT IN DERMATOLOGY

THEODORE CORNBLEET, M.D.

ALBERT H. SLEPYAN, M.D.

AND

MICHAEL H. EBERT, M.D.

CHICAGO

Mercury ointments in various forms have long been a standby for the dermatologist. First, metallic mercury ointments were employed, and in recent times the ammoniated mercury ointment has enjoyed tremendous vogue. In the last few years, calomel ointment has been used in the so-called clean inunction method in the treatment of syphilis.

Calomel ointment, first prepared in France during the last century, contained 10 per cent of calomel in petrolatum. The British used 20 per cent of calomel in lard. A 30 per cent ointment with white petrolatum was introduced into the National Formulary V (1926) under the name of Ointment of Mild Mercurous Chloride. In N. F. VI (1936) the base was changed to equal parts of white petrolatum and hydrous wool fat.

Dr. Lewis C. Britt,¹ chemist of the Oregon State Board of Pharmacy, first pointed out that the N. F. VI ointment gave a narrower inhibitory ring in the agar plate test for antiseptics than did the N. F. V ointment.

Mr. E. E. Vicher² at the University of Illinois College of Pharmacy undertook the study of the ointment.

Assisted by a grant from the American Pharmaceutical Association, From the University of Illinois College of Medicine (Dr. Cornbleet) and Rush Medical College (Dr. Slepian and Dr. Ebert).
1. Britt, L. C.: The Antiseptic Value of Calomel Ointment N. F. V. and N. F. VI, J. Am. Pharm. A. 26: 646-647 (July) 1937.
2. Vicher, E. E.; Snyder, R. K., and Gathercoal, E. N.: An Improved Calomel Ointment, J. Am. Pharm. A. 26: 1241-1245 (Dec.) 1937.

He developed calomel in which the particles were very small, 0.5 micron or less in diameter. This calomel in aqueous suspension with gelatin was incorporated into the ointment base. The new calomel ointment produced an inhibitory ring from three to six times as broad as did the official calomel ointment.

The improved or "colloidal" calomel ointment has been extensively investigated from the chemical, bactericidal, pharmacologic and toxicologic standpoints. It appears to be no more toxic than the N. F. ointment, which has never been considered as toxic for human beings in doses of 1 drachm (4 Gm.). It has a prophylactic value in syphilis at least equal to that of the N. F. VI ointment.

As it is not unreasonable to expect that a colloidal calomel application with its demonstrated efficiency as a superior bactericidal agent should find use in certain cutaneous disorders, this colloidal calomel ointment has been used in the dispensary of the dermatologic clinics of the Cook County Hospital to a sufficient extent to justify a preliminary report.

USE IN IMPETIGO CONTAGIOSA

We have found its greatest therapeutic value to be in impetigo contagiosa. In about 130 cases of this infection colloidal calomel ointment has served as an extremely efficient remedy. The use of ammoniated mercury ointment has long been a standard agent in impetigo, but all experienced dermatologists attest the observation that for some reason this medicament is not as efficient as it was in the past. According to our observations, colloidal calomel ointment clears the eruption in an average of one third to one half the time required by ointments of ammoniated mercury (chart). This is particularly gratifying since the colloidal calomel ointment is both cleanly and, so far as our experience goes, not toxic. In not more than three or four instances it has produced a slight irritation, but this was not great enough to necessitate its withdrawal. Its cleanliness is to be emphasized because it gains the patient's cooperation and makes it a favorite over other efficient agents, such as applications of gentian violet solution.

Colloidal calomel ointment was found useful in other superficial pyodermas in addition to impetigo. In ecthyma, the base of the lesion is so deep as to require removal of the overlying crust, whereupon the colloidal calomel ointment proves curative. In Bockhart's impetigo, which is a more superficial infection of the hair follicles than that in furunculosis, and in furunculosis itself, no benefit was obtained from the use of colloidal calomel ointment.

ERYTHEMATOUS DERMATITIS BEHIND EAR

There is a condition which produces a superficial erythematous dermatitis in the fold behind the ear which is diagnosed most often as seborrheic dermatitis and which some authorities think is due to a streptococcal infection. This is particularly resistant to treatment and especially so in that form in which the disease process reaches around to the front of the ear. In several cases of this disorder, the use of colloidal calomel ointment has been of benefit. It has been more effective than any other agent we have used.

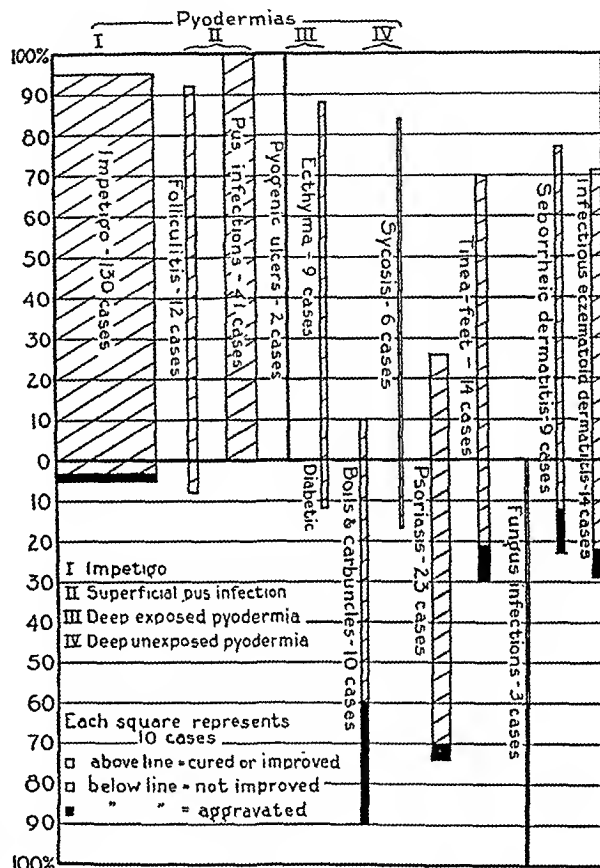

INFECTED LEG ULCERS

Three patients with leg ulcers which, by their appearance, were undoubtedly continued or aggravated by secondary pyogenic infection, received much benefit

from applications of colloidal calomel ointment. With no other treatment than the usual advice to the patient to remain off his feet as much as possible, these ulcers healed. In a number of other instances of leg ulcers on a basis of poor circulation, these applications were of no benefit.

OTHER DERMATOSES

Several patients with early psoriasis were benefited by applications of colloidal calomel ointment. It must be emphasized that these early cases are as a rule easily improved by ammoniated mercury ointment and that improvement with the calomel ointment represents no great triumph. In older cases of psoriasis and in the inveterate ones, colloidal calomel ointment did not improve the lesions.

Dermatoses treated with colloidal calomel ointment.

Since colloidal calomel ointment proved to be so efficient in some of the superficial infections, it was hoped that it might likewise be beneficial in the superficial fungous infections such as eczematoid ringworm. Unfortunately, colloidal calomel ointment did not influence these infections.

There is a relatively superficial, sharply defined, exudative, patchy dermatitis that occurs on the backs of the hands and forearms particularly, but which may appear elsewhere also, called infectious eczematoid dermatitis. This probably results from the secondary infection of an already irritated base. Several of these cases were improved by applications of colloidal calomel ointment. Two of them were irritated by this form of treatment, so that it had to be stopped.

A number of other dermatoses were treated with the colloidal calomel ointment more or less unsuccessfully.

There is no benefit from its use in lichen planus, paronychia due to yeast infections, pityriasis rosea, tinea circinata, lupus erythematosus or lupus vulgaris.

SUMMARY

Colloidal calomel ointment in this study was found to be a clean, unusually effective agent in impetigo contagiosa and related superficial pyodermas. Seborrhic eczema behind the ears, which is often quite resistant to treatment, was favorably influenced by applications of colloidal calomel ointment. It improved leg ulcers aggravated or continued by a secondary pyogenic infection; also some forms of seborrhic eczema and early cases of psoriasis. In other dermatoses, colloidal calomel ointment either was without benefit or proved to be irritating.

Clinical Notes, Suggestions and New Instruments

EIGHT YEARS DEPENDENCE ON A RESPIRATOR AN UNUSUAL CASE OF POLIOMYELITIS

SCOTT LORD SMITH, M.D., POUGHKEEPSIE, N. Y.

Seven years dependence on a respirator is an experience sufficiently unusual to warrant chronicle and comment. When the cause of such dependence is a case of acute anterior poliomyelitis with resultant massive paralysis involving practically all voluntary muscles below the clavicles and all automatic respiratory muscles with the exception of the right leaf of the diaphragm, the number and magnitude of the problems presented are all too evident. In these seven years the subject of this report spent more than half his time in the respirator, never acquiring a capacity to sleep and carry on respiration simultaneously. During this time three types of problems arose: (1) those immediately connected with his care, (2) those concerned with the physiologic changes occurring as a result of the extensive paralysis and (3) those involved in a study of his respiratory control. The first two of these problems will be discussed in this paper; the third is now under investigation. In order to show what problems arose in dealing with the acute illness, the maintenance of body function, the treatment of upper respiratory infection and pneumonia in one who could not cough, and the preservation of function of the few unimpaired muscles, a brief summary of the condition of the boy on admission to the hospital in September 1931 and at the end of each subsequent year will be given.

B. S., a boy aged 13 years, was admitted to the Medical Service of Vassar Brothers Hospital on the fifth day of an acute illness. A diagnosis of poliomyelitis was confirmed by a high cell count of the spinal fluid, and 60 cc. of immune serum was given at once intramuscularly. The patient was exceptionally well nourished and developed and was not at that time in immediate respiratory distress, although his extremely labored breathing was short, shallow, rapid and confined entirely to the diaphragm. The intercostal muscles did not move at all. The temperature was 103 F., the pulse rate 110 and the respiratory rate 30. The pupils were equal and contracted, reacting sluggishly to light. There was no paralysis of the ocular or facial muscles. There was no trouble in swallowing. The heart was rapid and regular except for an occasionally missed beat. The sounds were clear and without murmurs. The lungs were clear and the abdomen was normal except for the exaggeration of abdominal respiration. There was complete paralysis of all four extremities, the patient being able to move only the toes of both feet and to make slight motions with the left hand and forearm. The cutaneous reflexes were absent.

During the interval between the preparation of this report and its publication, the patient has completed his eighth year, with dependence on the respirator, without material changes over the preceding year. The studies on metabolic changes referred to in the first paragraph and made in collaboration with Prof. Elizabeth Magers, of the physiology Department of Vassar College, will shortly be published elsewhere.

Twelve hours after admission, increasing dyspnea and cyanosis demanded the use of the respirator and on the second day catheterization became necessary. As extreme cyanosis occurred within thirty seconds after the respirator was opened a team of four persons was required, a doctor to do artificial respiration, another to catheterize, a nurse to change the sheets and another to rub the back. Even with all four working simultaneously and at top speed, from three and a half to four minutes was necessary and the boy approached asphyxiation and unconsciousness.

For two days the temperature fell. It then rose to 108 F. and again dropped rapidly, ceasing to be significant. Persistent muscle twitching of the face, neck and left leg was troublesome from the first and continued during four weeks in all four extremities. This necessitated frequent sedatives. There was also extreme difficulty in establishing intestinal action, and for two or three days a paralytic ileus seemed about to occur. Gradually, however, the combined use of cathartics and enemas was successful. Poor appetite required feeding by tube. But after a few months the body became adjusted, the gastrointestinal tract resumed its normal functioning, appetite returned and ability to breathe improved. After seven months of paralysis a general upturn in physical condition was observable. Gradually the use of the auxiliary muscles, semivoluntary in character, made it possible for the patient to spend more and more time out of the machine. The only lessening of the paralysis, however, was in the wrist and finger of the left hand, in one finger of the right hand and in the flexor muscle of the left thigh. Movement was possible in these muscles only when the boy was in the bath.

In September 1932 the child could remain out of the respirator for eight or nine hours without undue fatigue. Fluoroscopic examination showed a right diaphragm with an excursion estimated at 2 cm. and a negative action of the left diaphragm. No motion of the intercostal muscles could be detected. The auxiliary respiratory muscles, especially of the scalenus group on the right side, seemed to have developed a semiautomatic action. Outside the respirator he was never able to sleep and could eat but little without experiencing a sense of fullness. There had been no changes in the affected muscles. His weight, which in the spring had been 73 pounds (33 Kg.), had increased to 92 pounds (42 Kg.). His general condition was good, his spirits were excellent. He enjoyed a daily tub bath, made trips about the hospital in a wheel chair and played several games adapted to his capabilities.

The second year was one of ups and downs. Dr. Drinker felt that it was important for the boy to regain self confidence and therefore advised that he be forced to discontinue sleeping in the machine. It was hoped that fatigue would eventually induce natural sleep. On one occasion he was kept out of the respirator for two and one half days until complete exhaustion forced a return to artificial respiration. Later we tried for several weeks having him remain outside part of every second night, but as there were progressive loss of weight, increased irritability and digestive upsets we abandoned attempts to force normal respiration during sleep. During most of this year he lost weight. In March and June there were periods of fever and infection of the upper respiratory tract, which were difficult to relieve and painful. Continuous artificial respiration, aspiration of secretions from the nasopharynx, morphine and ammonium chloride were found helpful.

On the afternoon of June 16, 1933, without warning of any kind, the slowly built-up ability to breathe with the auxiliary muscles, especially with the right scalenus group, suddenly ceased. Complaining of a lump in the chest, he became suddenly cyanotic. In the respirator he rapidly regained color and comfort. Examination showed that the voluntary auxiliary muscles of respiration, the contractions of which with each respiration had been visible a few hours earlier, had ceased to work on the right side, where they had been the strongest. Two weeks later muscular ability had again been built up and for an hour at a time he was able to breathe comfortably. In a month he could breathe alone for twelve hours. The left scalenus muscle group developed and soon exceeded the right ones in strength. This condition has continued.

In the early part of the third year the lost weight was regained. Thereafter, although there was no change in respira-

tory function he did well on his regular routine and was in good spirits. In a station wagon which carried his wheel chair he took many rides about the country and often went to the movies. Being away from the respirator gave him no apprehension, and he was able to eat well outside. Hay fever and eczema, however, caused considerable distress. Increase in alkalinity of the urine was accompanied by frequency and discomfort, which was readily relieved by the administration of ammonium chloride. Occasional hematuria accompanied by vesical irritation appeared for the first time.

During the year 1935 he continued to show symptoms of kidney stone, acute pain in the right lumbar region, hematuria, nausea and the passage of small "gravel" by the urethra. In April he had pneumonia, with consolidation in the left lower lobe. For nearly two weeks there was irregular fever up to 104 F., pain in the left side of the chest, and choking. Relief from thick mucus which he could not loosen was obtained by aspiration with a suction pump, oxygen being given with a nasal catheter. Gradually he made a complete recovery.

The fifth year was an uneventful one. An x-ray examination showed the presence of a stone in the right kidney pelvis. Two months later stones appeared in the left kidney pelvis and low down in the left ureter. Sex development was average for his age.

In 1937 the chief changes were psychologic. In general he lost confidence in himself and was fearful of being at a distance from the respirator, so that he gave up his frequent trips. He lost his former belief in his eventual recovery and in the value of living. He maintained, however, his interest in all athletic contests, in cross-word puzzles and in cards, checkers and chess.

The seventh year was without new development. The loss of morale, begun in the previous year, continued and increased. Through most of 1938 he did not leave the hospital grounds. There was increasing pain and hematuria from the renal calculi, which were seen by means of the x-rays to be increasing in size. For three months approximately 85,000 units of vitamin A was given daily. As the calculi had not decreased in size at the end of this period, this therapy was discontinued.

GENERAL PROBLEMS

Later in the fall of 1938, signs of eye strain became apparent. Glasses with a 3 degree prism base up, in addition to ordinary correction, raised the field of vision one foot nearer to the plane of direct vision. This procedure not only had the desired effect on his vision but caused a more important uplift of his general morale.

Deformities came on late and insidiously. A tendency to a lateral curvature of the spine became apparent when he first began to use a wheel chair in 1932, even though the shoulders were elevated only a few inches in order to give him an opportunity to look around. Sand bags and other means of correction proved ineffectual and uncomfortable and were abandoned. The resulting curvature has slowly increased in the last two years. Contractures of both hands appeared considerably later and became stationary.

Constant twenty-four hour nursing attention was maintained from the first and we were unable to find any way to dispense with it or even to combine the care of this boy with that of others. All changes in position of the body from the shoulders down had to be made by the nurse, and all parts exposed to pressure were kept cushioned with rings. As a means of maintaining a healthy condition of the skin the daily bath was begun as soon as respiratory function permitted. The old style portable typhoid tub served this purpose admirably. In addition the nurse had to feed him each mouthful; she also turned each page of the books he read and made the moves he indicated in playing games. She remained constantly within earshot, because we were unable to arrange a call system, and speech for him was possible only during one phase of the respirator action. Nursing care was exceeded in importance only by mechanical respiration.

The original respirator has been in service during the entire seven years, except for a period of two months when the motor blower exhaust was being replaced by bellows. These are much quieter and have the additional advantage of being operable by hand in an emergency. As fuses had blown out several times

when continuous operation was necessary, the manual operation was reassuring to the patient and his attendants although its use has never been required.

SUMMARY

At the time this is being written the subject of this report, a youth nearly 21 years of age and a victim of the 1931 poliomyelitis epidemic, has been dependent on a respirator, at least during sleep, for over seven years. He has been through the vicissitudes of colds, hay fever, eczema and pneumonia. He is still troubled by renal calculi, a continuously developing spinal curvature, and occasional mental depression. The nearly complete paralysis has given opportunity to study some of the concomitant metabolic changes.

SULFAPYRIDINE IN TRACHOMA

M. P. SPEARMAN, M.D., AND W. E. VANDEVERE, M.D.
EL PASO, TEXAS

To the growing list of diseases in which sulfapyridine may be found of use we should like to add trachoma. In two cases, herewith reported, we have observed astonishing improvement in the chronic form of the disease when treated with sulfapyridine.

REPORT OF CASES

CASE 1.—F. F., a white youth aged 15, first seen by us March 11, 1939, had been under treatment for trachoma elsewhere for about one year. Examination showed both corneas markedly opaque. There were no clear areas on either cornea. Vision in both eyes was fingers at 1 foot. Pannus was markedly developed on both corneas. The under surfaces of both upper lids were covered with follicles. The Wassermann and Kahn reactions of the blood were negative. The patient was hospitalized and massive doses of sulfanilamide were given. During the period of hospitalization, covering one month, about 1,000 grains (65 Gm.) of sulfanilamide was given. Local treatment with ophthalmic ointments, copper citrate and quinine bisulfate was given. At the end of one month the patient was discharged from the hospital only slightly improved. The patient went home, where he used only local treatment, consisting of ophthalmic ointment quinine bisulfate twice a day. On July 24 he was again seen at our office. No improvement was noted. At that time we prescribed sulfapyridine, $7\frac{1}{2}$ grains (0.5 Gm.) every four hours. August 5 we again examined the patient. The lower half of each cornea was found to be free from pannus and was completely transparent. The vision was 20/50 in both eyes. The under surfaces of the lids were smooth and free from irritation. The patient was told to continue the same dosage of sulfapyridine. August 26 we last saw the patient. At this time both corneas were almost completely transparent and all signs of pannus had disappeared. Vision was 20/30 in the right eye and 20/40 in the left eye (without glasses). There have been no toxic reactions to the sulfapyridine.

CASE 2.—G. U., a white man aged 49, admitted to our outpatient service at a local hospital Aug. 11, 1939, had been treated for trachoma for about five years. The Wassermann and Kahn reactions of the blood were negative. Every conceivable anti-septic had been used in the eyes. Two years before admission bilateral tarsectomy was done on the upper eyelids. Some months later a plastic procedure was performed for "entropion." Certain of the organic silver preparations had been abundantly used as instillations in the eyes, so that there was on admission a definite argyrosis of the bulbar and palpebral conjunctivas. Examination on admission showed marked opacity of both corneas, well developed pannus and deep scarring of the under surfaces of the upper lids but no trichiasis. Vision was fingers at 6 feet in both eyes. August 23 we prescribed sulfapyridine $7\frac{1}{2}$ grains every four hours. Examination of the eyes August 30 showed both corneas beginning to clear and the pannus lessening. September 6 the lower half of each cornea was becoming transparent; the upper portions were much less opaque, with tiny, scattered areas of transparency. The pannus had nearly disappeared in both eyes. Vision was 20/100 in both eyes.

COMMENT

While realizing that adequate conclusions cannot be drawn from clinical results obtained in only two cases, we nevertheless were greatly impressed with the remarkable remissions of pathologic signs obtained in two cases of chronic trachoma when sulfapyridine was given. Both cases had proved intractable to all other methods of treatment. Vision has improved greatly in both cases. We plan to continue our present treatment at least until maximum improvement, both subjectively and objectively, is obtained.

CONTACT DERMATITIS DUE TO MANGO

SAMUEL J. ZAKON, M.D., CHICAGO

CASE 1.—A 29 year old woman presented an acute vesicular dermatitis of three days' duration which involved both lips and a moderately large circumoral area. There was no history of contact with any of the common substances usually responsible for a dermatitis in this location. She stated that two days prior to the onset she received a case of mangoes from her father, who owns a fruit farm in Florida. About twenty-four hours after eating a mango itching developed about her mouth, and her lips began to swell.

Examination revealed an erythematovesicular eruption involving both lips, the chin and both cheeks. The lips were edematous and she had difficulty in opening the mouth. There were no lesions on the mucous membranes of the mouth. The patient stated that she felt nauseated after eating the mangoes. Her past history is irrelevant with the exception that she had had attacks of urticaria after the ingestion of strawberries.

Patch tests performed on the patient's back using mango peel and juice proved that only the peel produced a positive reaction.

CASE 2.—A 19 year old girl presented an acute erythematovesicular eruption of twenty-four hours' duration on the lips, nose, face and neck. There were extreme burning and itching. The patient felt nauseated and complained of a moderate headache. There was no history of contact with any of the materials usually suspected when an eruption involves this area, such as cosmetics, mouth washes or tooth pastes. There was a history of eating a mango twenty-four hours before the onset of the eruption. Other members of the same family who ate mangoes were unaffected.

Examination revealed marked edema about the lips and a dull red erythema studded with discrete vesicles and bullae about the face. The previous history is essentially irrelevant with the exception that six months prior to this attack a dermatitis which was due to dress shields developed in the axillae.

Patch tests with the peel and juice of the fruit produced a positive reaction to the peel and not the juice.

In both cases the condition cleared up within ten days with mild local therapy.

COMMENT

The fruit of the mango has recently become popular as a delicacy in many parts of the United States. According to Kirby-Smith,¹ the peel before ripening contains a substance which affords protection from the attacks of insects. This substance remains so active in some varieties, even after the fruit has ripened, as to affect some people eating the fruit with what is known as "mango poisoning."

The mango belongs to the species *Mangifera indica*. Its home is believed to be India, Burma and Malaya and it is known as the "apple of the tropics." The fruit varies from oval to S shape, weighing from 8 to 38 ounces. It has a relatively smooth peel with a single large seed and when ripe is usually greenish yellow.

Mango dermatitis as defined by Kirby-Smith¹ is an irritation of the skin and mucous membranes produced in susceptible

persons by contact with the resin from the peeling or stem of the fruit or with the sap of the tree. The sites usually affected are the lips, face and hands. Depending on the susceptibility of the individual and the amount of exposure, the lesions vary from mild dermatitis to severe disfiguring edema and even to prostration.

The mango and the poison ivy both belong to the family Anacardiaceae. The dermatitis caused by eating the mango fruit may be compared to that of *Rhus venenata*.

CONCLUSIONS

An acute vesicular or bullous dermatitis and marked edema about the mouth may be caused by eating mango fruit. With the increasing use of this fruit in the daily diet, the mango should be seriously considered as an etiologic factor in acute dermatitis of the face.

Special Clinical Article

THE TREATMENT OF THE PATIENT
WITH SEVERE BURNS

CLINICAL LECTURE AT ST. LOUIS SESSION

ROY D. McCLURE, M.D.

DETROIT

In 1937 there were almost 8,000 deaths from fire in the United States. Forty-five per cent of lethal burns are in children under 6 years of age, and in Penberthy's¹ series of 493 cases at the Children's Hospital in Detroit it was found that 80 per cent of these should be considered avoidable. We, as physicians, should take a prominent part in a program of safety education directed toward preventing this needless loss of life.

It is now fifteen years since Davidson² began his revolutionary work on burns while he was resident surgeon at the Henry Ford Hospital. This period marked the inception of a method of treatment which many of us believe is the best available at the present time, but more significant was the sudden arousal of interest in the subject of burns among physicians throughout this country and abroad. The number of papers on burns during the ten year period following his original communication was three times that of the preceding ten year period. Many variations in the treatment have been promulgated which, in the hands of their sponsors, show results comparable with the best that prevail today. These variations should not be allowed to confuse the average physician, who in the aggregate cares for the great mass of all burn cases, from meticulous attention to the essential principles of treatment, which I shall attempt to outline.

In view of the careful clinical and experimental work that has been done recently, it is desirable to pause and take stock of the present available information. Answers to the following questions should be sought:

1. Are there any new facts concerning the systemic effects of the chemical and tissue changes which follow severe burns?

From the Department of Surgery of the Henry Ford Hospital. The author acknowledges the assistance of Dr. C. R. Lam in the preparation of this paper.

Read in the Surgical Division of the General Scientific Meetings at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 16, 1939.

1. Kirby-Smith, J. Lee: Mango Dermatitis, *Am. J. Trop. Med.* 18: 373-384 (July) 1938.

2. What is the effect on the mortality rate of present methods of treatment?

3. In the light of our present knowledge, what is the best therapeutic procedure in burns?

Research on burns has been largely concentrated on explaining the so-called toxic phase, which appears after eighteen to twenty-four hours. Three theories have arisen:

1. First is the physical, which assumes that there is local leakage of fluids and plasma proteins, with resulting blood concentration and circulatory failure. This has been shown by Underhill,³ Blalock,⁴ and Harkins.⁵ At the 1937 session of the French Surgical Congress, where Allen and I⁶ reported the experience with tannic acid in this country, the trend was markedly toward the theory of a soluble toxin. All agree on the importance of loss of plasma protein, but it is probably not the lethal factor.

At this time I shall mention the possible role of tissue anoxia in burns. Underhill stated: "Marked concentration of blood means a failing circulation, an inefficient oxygen carrier, oxygen starvation of tissues, fall of temperature, and finally suspension of vital processes." This statement is interesting in view of the recent advances in the knowledge of anoxic lesions produced by barbiturate poisoning, acute alcoholism, anesthetics and other factors, as exemplified by the recent work of Hartman⁷ of our staff.

2. Then there is the bacterial theory of Aldrich.⁸ At the Johns Hopkins Hospital he took cultures of a large series of burns, and at the end of eighteen hours he found beta hemolytic streptococci in most of them and invariably found these organisms in the blood and burned areas in fatal cases. Aldrich remains the chief proponent of the theory, stating in 1937:⁹ "For let me add again, where there is no infection, there is no toxemia." A recent report from Edinburgh¹⁰ casts considerable doubt on Aldrich's theory. This report represents the experience with 200 burns, sixty-five of which were serious. There were twenty autopsies. Careful bacteriologic work was done on the burns with aerobic and anaerobic cultures. Frequently, cultures of representative areas showed no growth up to ninety hours. These authors stated that the evidence was against bacterial infection as the cause of the acute toxemia. "Certainly, there was rarely any evidence that hemolytic streptococci were flourishing in the burned area and invading the blood stream. Moreover, hemolytic streptococci were sometimes grown in pure culture from isolated portions where systemic disturbances were entirely absent."

At the Henry Ford Hospital we have been unable to convince ourselves that bacterial invasion is the significant factor in the early acute toxemia. However,

we added an antiseptic, hexyl-chloro-resorcinol, to the tannic acid after the work of Hartman and Schelling¹¹ showed the efficient bactericidal power of such a combination.

3. The third theory is that a specific toxin is formed at the burned area which is absorbed and distributed by the circulating blood, with the resultant picture of toxemia and collapse. This is the oldest theory, and it came into disrepute when Underhill pointed out the fallacies of certain previous experimental work¹² and produced evidence that there is poor absorption from burned areas. As has already been stated, the toxic theory is regaining favor. Mason and his co-workers¹³ noted no difference in the absorption of potassium iodide that was injected subcutaneously into normal tissue or into burned tissue. Mason, who worked with Davidson on the question of tissue autolysis, maintains that "death occurring several days following severe burns is due mainly to the absorption of protein decomposition products." Wilson and his collaborators¹⁴ removed the tissue fluids from edematous burned tissues forty-eight hours after the burn. They found that this fluid had acquired toxic properties and was frequently fatal to healthy animals of the same species. Rosenthal¹⁵ tested the blood of burned pigs, guinea pigs and human beings and found a histamine-like substance, which was first linked with the red cells but was later found in the serum. It differed in several ways from histamine.

PATHOLOGY

The chief addition to our knowledge of the pathology of burns since the early article of Bardeen¹⁶ in 1898 has been the emphasis on the changes in the liver. Marked necrosis of liver cells has been noted in many cases of fatal burns. This lesion was especially impressive in two cases recently under treatment. Two men climbed down into a tank which had been used to store oxygen and began to work with an acetylene torch. Their clothing suddenly burst into flames. They were able to climb out of the tank and fellow workers extinguished the fire. Second and third degree burns were sustained, which amounted to one half of the body surface of one man and one fourth of the other. In spite of intensive treatment, the man with the larger burn died in profound toxemia on the third day. Post-mortem examination showed almost total necrosis of liver tissue, shown by microscopic section in the accompanying illustration. The other man showed toxemia to a less marked degree, but the liver became palpable and jaundice appeared, the icterus index rising to 130 units. Large amounts of intravenous dextrose were given to promote regeneration of the liver, with the result that he recovered without disability.

We agree with Wilson,¹⁰ who stated: "In summary, we may say that after death from burns a lesion of the liver cells was found in many cases which was characteristic of this form of injury. Its relation to acute

Rep.* 7: 137-179, 1898. Since this paper was read, an excellent report on liver necrosis in burns has appeared by T. H. Belt (*J. Path. & Bact.* 48: 493-498 [May] 1939).

toxemia was so remarkably close as to leave little doubt that the liver lesion and the acute toxemia were produced by the same mechanism. The responsible agency was certainly not bacterial infection, and in our view the liver lesion furnished the strongest evidence of a nonbacterial toxin circulating during the first few days after a burn." This reservation must, however, be made: these changes may be due to anoxia.

CHEMICAL PATHOLOGY

It is well known that there are changes in the blood chemistry in severe burns. The most constant is blood concentration, as expressed in the hemoglobin determinations and hematocrit readings. However, we have all seen cases in which the hemoglobin content has been kept at a normal level or below by intensive administration of fluid, and yet we have watched such cases proceed to death in a state of toxemia.

Based on her own investigations and those of Dr. Alfred Blalock and Dr. Anne Minot at Vanderbilt Uni-

Section under medium power of liver of burned patient who died on third day after being burned. Extensive necrosis in center of the liver lobule, with a zone of intact liver cells in periphery (lower part of section).

versity School of Medicine, Dr. Katharine Dodd¹⁷ suggests the great importance of replacing promptly the large amount of circulating protein that is lost in severe burns. This is done by serum transfusions. The mere replacement of water and salt as such will only serve to make matters worse by diluting the concentration of the protein that remains in the blood vessels. If too great a depletion of plasma volume occurs, the blood pressure falls precipitately and fatal shock ensues. It would seem better, therefore, to rely on frequent hemoglobin or hematocrit determinations and measurement of serum protein concentration than to use the systolic blood pressure as a gage of a burned patient's condition.

Other blood constituents that show variations from the normal are the chlorides, plasma proteins, carbon dioxide combining power, nonprotein nitrogen, sodium and potassium. There is good evidence to indicate that no one of these factors is a determinant in fatal cases, although further work must be done to evaluate fully the

behavior of the basic ions. Nevertheless, measures to restore the blood chemistry to normal should be carried out in order that the burned patient may be given all possible assistance during the early critical days.

MORTALITY STATISTICS

In 1935 Allen and I¹⁸ reported the status of burns after ten years' use of Davidson's method. We called attention to the fact that the Bureau of Census mortality statistics for the United States registration area showed a decrease in 1933 from the previous high figures. In 1928 there were 8,083 deaths from burns (the highest during the decade) and in 1933 there were 5,232 deaths. I regret to report that in the succeeding four years there has been no further reduction.¹⁹

The figures in the accompanying table are difficult to reconcile with the reports of the lowered mortality rates which come from various institutions. In our paper Allen and I showed a table which indicated the reduction in mortality in several centers. To this may be added the report of Mitchiner.²⁰ At the St. Thomas Hospital, London, there was a mortality of 15.5 per cent in the period 1924-1928 when picric acid was used, and a mortality of 4 per cent in the period 1929-1936 when the Davidson method was used. The mortality from scalds was reduced from 7.5 per cent to 1.7 per cent. At the Children's Hospital in Toronto Harris²¹ noted a fall in the death rate from 26.6 per cent to 12 per cent, and Herzfeld,²² at the Royal Edinburgh Hospital for Children, had a reduction of 38 per cent to 9 per cent.

In evaluating the Davidson treatment, in addition to the mortality statistics, one should consider the economic factor of great saving in amount of dressings, shorter stay in the hospital as well as the relief of pain, and the diminution of scarring and gross deformities.

TREATMENT

In the management of a severe burn, two fundamental principles must be observed. These are the prevention or treatment of shock and the carrying out of scrupulous aseptic technic in the local treatment of the burned area, which should be regarded as a large open surgical wound. The advent of the tannic acid treatment of burns was so revolutionary in character and its immediate effects so dramatic that attention has been focused on local applications alone, while the auxiliary treatment of shock has too often been neglected. This state of affairs can be explained by the fact that, except in the larger cities, the opportunity to treat severe burns is rarely presented to the practitioner. In the United States in 1937 alone there were 5,466 deaths from burns. If these cases were equally distributed among the 130,000 practicing physicians, each would have had under his care only one fatal case in more than twenty-three years of practice, and if the mortality should be placed at 20 per cent, this would mean that, on the average, each physician would treat one patient with severe burns every four and one half years. It is not surprising, therefore, that the average physician is not familiar with all the details of treatment. For his benefit, the following summary of treatment is inserted:

TREATMENT OF BURNS—HENRY FORD
HOSPITAL METHOD

It is important to bear in mind the necessity of treating the patient as well as the wounds. Treatment naturally resolves itself into three phases: supportive measures, local treatment of the burned areas, and after-care.

General Supportive Measures.—These are largely directed toward the control of symptoms.

1. Pain and restlessness are combated by adequate and repeated sedation.

2. Oxygen therapy may be indicated in certain severe cases.

3. External heat is applied: hot water bottles and blankets if the burned area is limited; in extensive burns, the electrically heated cradle tent and super-heated room.

4. Restoration of fluid balance is undertaken. The aim of fluid administration should be to obtain a twenty-four hour urinary output of 1,500 cc. Fluids are given by mouth if tolerated, by rectum, interstitially and intravenously. The continuous intravenous method is often indicated and may be imperative in cases of extensive burns involving the extremities. The solu-

Deaths from Burns, 1933-1937¹⁰

Year	Deaths from Burns*
1933	5,232
1934	5,758
1935	5,687
1936	5,971
1937	5,466

* These figures exclude deaths classified as due to conflagration, where suffocation or cremation may have occurred, and those due to special accidents, such as mine accidents. In 1937 there were 1,688 deaths due to conflagration and 774 deaths from special accidents, a total of 7,928 deaths by fire.

tions used are 5 per cent dextrose and physiologic solution of sodium chloride.

5. Blood plasma transfusions are done. Whole blood should be used only when blood concentration is normal, as indicated by repeated hemoglobin or hematocrit determinations. When hemoglobin values of more than 15.6 Gm. are obtained, plasma transfusions should be given.

6. Laboratory investigations are made:

(a) Frequent hemoglobin or hematocrit determinations should be made.

(b) The urine should be analyzed frequently, with determinations of the specific gravity and albumin content.

(c) Serum protein determination should be made immediately on admission.

When facilities are available, the following procedures should be done:

(d) Chloride estimations should be made at intervals so that depleted chlorides may be restored by intravenous administration of saline solution.

(e) Blood cultures may be taken.

(f) The nonprotein nitrogen should be determined.

(g) The icterus index should be ascertained as a means of recognizing toxic hepatitis or liver damage.

Local Treatment.—1. Remove all clothing under as sterile conditions as possible and place the patient on sterile sheets in a warm room.

2. Take all precautions to avoid infection of the burned area. Treat it just as any other large wound.

All dressings and applications must be done under aseptic conditions—masks, gloves and gowns must be worn by doctors and nurses.

3. Débridement should be minimal and should be limited to opening blisters and cutting away dead skin.

4. Tannic acid in a 5 per cent fresh solution is applied with an atomizer or power spray. This is a simple and effective way of tanning the burned area. This solution is sprayed on at frequent intervals until the burned area is thoroughly tanned. Ointments containing tannic acid plus an antiseptic are useful in small burns and for burns of the face and the perineum. The addition of antiseptics such as resorcinol or silver nitrate to the tannic acid with the idea of preventing infection has been employed with apparent success, but treating the burned area as a surgical open wound by taking steps to prevent the introduction of infecting organisms is an equally, if not more, effective measure.

After-Care.—1. Cut away all dead skin and open collections of fluids under aseptic precautions and then again spray tannic acid on the bared areas.

2. As the heavy tanned crust forms, watch carefully for local signs of infection under the crust and liberate collections of pus. Occasionally the first clue to these collections is evidence of systemic reaction.

3. Prevent contracture deformities by the early use of extension apparatus.

4. Employ skin grafting early and freely.

5. Detect and treat secondary anemia early. Blood transfusion is the best method of doing this in the late stages.

COMMENT

We have continued to advocate the use of tannic acid in the local treatment of the skin. Variations in the technic have been successful.²³ Other eschar-forming chemicals, such as gentian violet and silver nitrate, have given satisfactory results. The advantages claimed are that the coagulum forms more quickly and is thinner and more pliable than that produced by tannic acid. Bettman²⁴ has had excellent results with a combined tannic acid-silver nitrate treatment. He believes that the combination is superior to tannic acid alone, and his experience would tend to bear out this contention. He attributes the improvement to the increased antiseptic qualities of the mixture and to the fact that the coagulum is produced without delay. We have found that the tannic acid may be conveniently applied to the medium of a water-soluble jelly to which has been added an antiseptic of the resorcinol group.

SUMMARY

The original theory that a toxin is formed in the burned area, from which it is absorbed and carried by the circulation throughout the body, with the production of systemic effects has not yet been settled. In spite of excellent results being obtained in many centers, the death rate in the United States seems to have reached a plateau far above that lower level which is possible with our present knowledge. Disagreements regarding the proper local treatment should not distract our attention from the more important problem—the treatment of a very sick patient who has a threatening toxemia, alterations in the blood chemistry, a wound very sus-

ceptible to infection and pathologic changes in organs remote from the skin. The greatest good can, of course, come through preventing burns from occurring, and I believe that the family physician, through his teaching in the home, can accomplish more than any other agency in this respect.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
HOWARD A. CARTER, SECRETARY.

CLARK DUPLEX INHALATOR ACCEPTABLE

Manufacturer: Physician's Oxygen and Supply Company, Inc., 1390 Eastern Parkway, Brooklyn.

The Clark Duplex Inhalator is designed to supply a mixture of carbon dioxide and oxygen for resuscitation of victims of gas poisoning, smoke poisoning, drowning and other conditions requiring resuscitation. It provides two cylinders with attachments for using the inhalator on two patients simultaneously. In case the supply from the small cylinders proves insufficient for longer periods of operation, a larger size tank may be attached by a third connection. The unit with cylinders weighs 47 pounds out of the case and 62 pounds when weighed with the case. The outside dimensions of the case are 25½ inches long, 13 inches high and 9¼ inches deep.

One cylinder contains a 7 per cent and the other a 5 per cent carbon dioxide mixture with oxygen. The change of administration from 7 per cent to 5 per cent or vice versa depends simply on the opening and closing of one or the other cylinder valve. The cylinders are of 16 cubic feet capacity and deliver upward of 75 liters of gas per minute each. The firm also supplies cylinders of 110 cubic feet capacity if desired.

Clark Duplex
Inhalator.

The apparatus was investigated by the Council. It was found that the cylinder attachment ports are provided with check valves which prevent leakage from a cylinder in use during removal of an empty cylinder or cause equalization in pressure between two cylinders if the two are open at the same time. These valves have been tested and found to function as intended. Gas from the cylinders passes through a reducing valve. This valve is set by the maker to reduce pressure to one of about 65 pounds per square inch. A gage reading to 3,000 pounds per square inch is provided for checking the content of cylinders.

The reducing valve is provided with two safety devices to prevent the building up of dangerous pressures in case of failure of its normal mechanism: (1) In the heavy bronze casing of the reducing valve there is a small frangible disk which will rupture at a pressure of about 500 pounds per square inch and (2), should this fail to break at this pressure, the thin metal bellows, which normally operates the reducing valve by its collapse and expansion, will rupture and allow the gas to escape through an aperture plug.

If there should be a continuous free flow of oxygen from the two cylinders at once, there would result a rapid emptying of these small portable cylinders. The features peculiar to this device are largely directed toward effecting oxygen economy, however. Directly below the reducing valve is a large rubber bag, called by the makers a "breathing bag." This is in no sense a rebreathing bag. Inside this bag is a vertical lever the long arm of which is connected to the middle of the bag. The short arm operates a valve which admits oxygen from the low pressure side of the reducing valve to this rubber bag. When the bag fills to a predetermined volume the movement of the lever closes the valve. Since no great pressure is required to distend the bag to this extent, the bag virtually functions as a second sensitive reducing valve and reservoir from which the patient or patients breathe the gas. From this point on, the equipment is in duplicate.

There is a valve delicately balanced against a spiral hair spring which is opened by the small pressure within the rubber bag as soon as the pressure within the face mask and breathing tube is reduced slightly below atmospheric pressure by an inspiratory effort of the patient or by the corresponding part of the cycle of artificial respiration. The stem of this valve is geared to an indicating needle, which moves over a dial and indicates the depth of respiration. These devices were tested in a laboratory in duplicate and found to operate satisfactorily. The face masks are provided with inflatable soft rubber edges for effecting gas-tight contact with the face and provided with elastic holding bands. The metal connection for attaching the corrugated rubber breathing tube carries the exhalation valve. A careful test was made to determine whether powerful exhalation would force any appreciable quantity of exhaled air into the rubber bag. It was found that practically all of the air escaped through the exit valve at the mouthpiece. When used as described, oxygen is fed into the mouthpiece only when the valve which actuates the breathing depth indicator is operated by inspiratory efforts. A lever at the side of the depth-of-breathing indicator case may be turned up, leaving this valve fully open. Oxygen then flows freely to the mouthpiece, and the indicator needle remains fully deflected. Oxygen in excess of that breathed escapes by the mouthpiece exit valve.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Clark Duplex Inhalator for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
PAUL NICHOLAS LEECH, SECRETARY.

**AMPOULES SODIUM CACODYLATE INTRA-
VENOUS-UPJOHN, 0.45 Gm. (7 grains), 5 cc.,
and AMPOULES SODIUM CACODYLATE
INTRAVENOUS-UPJOHN, 1 Gm. (15½
grains), 10 cc., NOT ACCEPT-
ABLE FOR N. N. R.**

The Upjohn Company presented these ampules of sodium cacodylate (among others) for consideration as to inclusion in New and Nonofficial Remedies. From the names on these packages it is apparent that they are for intravenous use. The Council holds that the desired effects of sodium cacodylate may be achieved by oral administration of the drug or, in exceptional cases, that the intramuscular route may be desirable. The Council has on other occasions pronounced similar dosage forms unacceptable (*THE JOURNAL*, May 7, 1932, p. 1654; Dec. 23, 1933, p. 2050).

The Council was therefore obliged to hold Ampoules Sodium Cacodylate Intravenous-Upjohn, 0.45 Gm. (7 grains), 5 cc., and Ampoules Sodium Cacodylate Intravenous-Upjohn, 1 Gm. (15½ grains), 10 cc., not acceptable for inclusion in New and Non-official Remedies. This does not apply to Ampoules Sodium Cacodylate-Upjohn for intramuscular use.

**DIMENFORMON AND DIMENFORMON BEN-
ZOATE (ROCHE-ORGANON, INC.) NOT
ACCEPTABLE FOR N. N. R.**

Dimenformon (Estradiol) and Dimenformon Benzoate (Estradiol Benzoate) of Roche-Organon, Inc., are partially synthesized products which are claimed to be effective estrogens. It is not the purpose of this report to criticize the quality of Roche-Organon estrogenic products, but exception is taken to the unethical and undesirable advertising methods used in the promotion of these estrogens to the physician. In a recently distributed circular on "Effective Estrogenic Therapy" there are listed about thirty or more "indications" for estrogenic therapy with Dimenformon and Dimenformon Benzoate "based on a very careful study of published clinical data augmented by private clinical

reports." Among the conditions for which the firm recommends estrogen therapy based on "very careful study" are leg ulcers, Buerger's disease, polyarthritis, certain ocular diseases and other disorders which have little or no endocrine relationship.

Physicians, even those having no special knowledge of the endocrines, may readily recognize the lack of scientific evidence for these therapeutic claims, and a detailed discussion of these recommendations would therefore be superfluous.

Other disorders, however, which bear some relation to the endocrine glands are being exploited by Roche-Organon (and other pharmaceutical houses) in a more subtle manner. For instance, estrogenic therapy of menstrual disorders has been the subject of considerable experimental work ever since the estrogens have been made available clinically. Except for the conditions of menopause (artificial or spontaneous) little progress has been made in the effective treatment of such disorders. Many of the reports on the clinical experimental use of estrogens have been unscientific and worthless; others demonstrate results which raise doubts as to their reliability. Many of the claims advanced by Roche-Organon appear to be based on such uncontrolled and unconfirmed reports.

Physicians well realize that the physiology of menstruation is at present only partially understood. It is true that uterine bleeding can be induced in the castrate by means of estrogens, but there are certain features of spontaneous normal menstruation which are subject to speculation and have not been satisfactorily explained as yet. It is no wonder, therefore, that disorders of menstruation are even less well understood. Functional dysmenorrhea, for example, has no established etiologic factor in most instances, despite the numerous theories concerning the role of the absence of corpus luteum, excess of estrogen, infantile uterus or neurogenic disorder. There are probably several types of dysmenorrhea and the outright recommendation that estrogens are of value in dysmenorrhea, in general, indicates a lack of understanding of this problem. Many factors, doubtless, are involved in the etiology of functional menorrhagia. The fact that excess bleeding can occur in the presence of a hyperplastic secretory or a resting endometrium is evidence of the different types of ovarian function associated with this condition. Similarly, amenorrhea may occur with either resting, hyperplastic or secretory endometrium, illustrating again the multiplicity of phases of ovarian activity associated with menstrual disorders. On the face of the matter, therefore, it is highly unreasonable to believe that one substance (estrogen) can alleviate or cure menstrual disorders ranging widely from amenorrhea to menorrhagia, including dysmenorrhea.

Other conditions for which estrogens have been advocated after the "careful studies" of Roche-Organon are on an even less sound basis. Toxemias of pregnancy, mastopathies, prematurity in infants, migraine and pituitary dysfunctions have all received one or more trials with estrogens. There is a definite lack of adequate confirmatory evidence in most of these reports. The rationale for estrogenic therapy here is usually quite flimsy, based mainly on assumption and imagination. The exercising of even mild discrimination would at least result in the acknowledgment that estrogenic therapy in these conditions is still mainly experimental.

The uncritical attitude of this firm is characterized by some of the statements appearing in its advertising matter. Thus, estrogens are suggested for the treatment of primary amenorrhea "of uncertain origin" and vaginitis of "non-specific" etiology occurring in children (!) Such a recommendation implies, in effect, that one is justified in prescribing treatment (estrogenic) when in doubt.

Matching the boldness of the suggestions for estrogenic therapy is the advice on the actual treatment of these conditions. In columns adjoining the recommended indications, the exact dosage of hypodermic and oral estrogens and any auxiliary treatment recommended is stated. The presence of printed figures on dosage gives an air of undisputed authority and finality to the recommendations. It would be interesting to learn of the sources from which the data were obtained. Especially valuable would be the firm's references on oral therapy since the reports in the scientific literature are relatively few. Not only should the accuracy of the information be challenged, but the physician should resent the aggressiveness of this firm in advertising in detail so-called instructions in a field of therapy

which is as controversial and unsettled as the one in question. Reliable information of this nature may be found by consulting scientific publications, and the usurpation of their function by commercially minded institutions should not be condoned.

Too much has already been made of the mysteries of endocrinology. It would be safe to say that the so-called mysteries and complexities are merely reflections of our present lack of knowledge of glandular physiology and therapy. Such a condition usually results when it is attempted to explain many phenomena on the basis of few facts. Much of our uncertainty has arisen from the discrepancies and unreliability of some of the endocrine literature. The result has been confusion and misunderstanding. Some of the manufacturers of pharmaceuticals have not been unaware of this state and undoubtedly have profited much from it. The advertisement "Effective Estrogenic Therapy" (Roche-Organon) is a clear example of the meretricious appeal to those physicians who are in no position to evaluate the recently expanded endocrine literature.

The Council voted that Dimenformon and Dimenformon Benzoate (Roche-Organon, Inc.) be declared unacceptable for inclusion in New and Nonofficial Remedies because of the exaggerated and unwarranted advertising claims with which they are marketed.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

RACEPHEDRINE.—Racemic Ephedrine.—d-1-Ephedrine.— $C_{10}H_{15}ON$.—d-1- γ -hydroxy, β -methylaniline phenyl propane. *Actions and Uses.*—The same as those of l-ephedrine.

Dosage.—From 30 to 50 mg.

Racephedrine is a colorless, crystalline substance. The melting point of the free base is 79 (microscopic heating stage). It is readily soluble in water, alcohol and ether. Weigh out, accurately, 0.2 Gm. of racephedrine and transfer to a desiccator over phosphorus pentoxide for fifteen hours at room temperature; the loss of moisture is not more than 0.5 per cent. Incinerate 0.1 Gm. of racephedrine, accurately weighed, and previously dried to constant weight; no residue remains. Dissolve approximately 0.5 Gm. of racephedrine in 20 cc. of water; the aqueous solution does not show optical activity and does not give the U. S. P. XI chloride or sulfate test.

For further identification see under racephedrine hydrochloride (*The Journal*, April 1, 1939, p. 1257).

Transfer 0.25 Gm. of racephedrine, accurately weighed, and previously dried over phosphorus pentoxide for five hours at room temperature; to a beaker. Add 10 cc. of distilled water and titrate with 0.1 normal sulfuric acid in a slight excess, using methyl red as indicator. Back-titrate with 0.1 normal sodium hydroxide. Each cubic centimeter of 0.1 normal sulfuric acid is equivalent to 0.01651 Gm. of anhydrous racephedrine.

Racephedrine-Gane's Chemical Works, Inc.—A brand of racephedrine-N. N. R.

Manufactured by Gane's Chemical Works, Inc., New York. No U. S. patent or trademark.

RACEPHEDRINE SULFATE.—Racemic Ephedrine sulfate.— $C_{10}H_{15}ON.H_2SO_4$.

Actions and Uses.—The same as those of l-ephedrine sulfate.

Dosage.—From 30 to 50 mg.

Racephedrine sulfate is a colorless, crystalline substance. The melting point is 247 C. (microscopic heating stage). The solubility is fair in water and alcohol. Dissolve 0.5 Gm. in 25 cc. of distilled water. The aqueous solution is neutral to litmus and does not show optical activity. The U. S. P. XI test for chloride is also negative. Weigh out accurately 0.25 Gm. of racephedrine sulfate and dry to constant weight over sulfuric acid in a desiccator at room temperature; the loss is not more than 2 per cent of its weight; 0.25 Gm. of racephedrine sulfate has a negligible ash residue. The assay for anhydrous racephedrine, as described in racephedrine hydrochloride, is not more than 77.5 per cent nor less than 75.5 per cent.

Racephedrine Sulfate-Gane's Chemical Works, Inc.—A brand of racephedrine sulfate-N. N. R.

Manufactured by Gane's Chemical Works, Inc., New York. No U. S. patent or trademark.

SUPRARENIN (See New and Nonofficial Remedies, 1938, p. 232).

The following dosage form has been accepted:

Tablets Suprarenin, 0.02 Gm.: Each tablet contains suprarenin bitartrate 0.0364 Gm., equivalent to suprarenin 0.02 Gm., with lactose 0.0385 Gm., and acetone sodium bisulfite not more than 0.0001 Gm.
Prepared by Winthrop Chemical Co., Inc., New York, N. Y.

THE PLUMMER-VINSON SYNDROME AND CANCER

The Plummer-Vinson syndrome, which appears to occur mostly if not exclusively in women, is characterized by hypochromic anemia, with or without achlorhydria, dysphagia and chronic inflammatory and atrophic changes in the mouth, pharynx and upper end of the esophagus. According to the observations of Ahlborn¹ at Radiumhemmet in Stockholm the syndrome brings with it a special liability to cancer in those structures. As a rule the afflicted women are poorly developed and poorly nourished; weakness and anemia may have existed for years, the first symptoms commonly appearing at the ages of from 18 to 20; sometimes anemia, sometimes dysphagia is the more prominent; in the milder forms the dysphagia may be missed easily by the clinician. All observers agree that, while liver preparations are without curative effect, iron in large doses leads to improvement, even to apparently complete recovery; only too frequently the anemia returns and the dysphagia may become more or less continuous for years. Such patients eat slowly and swallow only a little at a time; occasionally only liquids can be swallowed; there may be choking spells due to spasm. In addition to the anemia and dysphagia there develop, as is true also in some degree in pernicious anemia, chronic inflammatory and atrophic changes in the lips, the tongue and the buccal and pharyngeal mucous membranes as well as in the upper part of the esophagus, the entrance to which is narrowed. These membranes become dry and inelastic, the tongue smooth and glazed, the lips thinned, stiff and cracked at the corners, the face gradually taking on a characteristic change. Early loss of teeth is common. Buccal leukoplakia may develop and the nails may turn spoon shaped (koilonychia). In about one fourth of the cases the spleen has been found to be enlarged. No systematic studies

appear to have been made of the blood chemistry, the metabolism or the structural changes in cases of the syndrome. In a case in which death occurred from puncture of the esophagus by a filiform bougie, Suzman² found hyperkeratinization of the oropharyngeal mucosa, lymphoid infiltration in the submucosa and atrophy of the muscular coat—changes currently regarded as "precancerous." The real nature and cause of the Plummer-Vinson syndrome or disease are not known; all observers agree that it concerns a nutritional deficiency or imbalance in which the lack of iron plays a part of fundamental importance as indicated by its curative action, but no deeper studies appear to have been made into the genesis of the condition. The limitation of the disease to women suggests that it is connected in some way with functions, endocrine and otherwise, peculiar to women.

The occurrence occasionally of cancer in women suffering from the Plummer-Vinson syndrome has been noted by several observers.² On the basis of a study of the rich clinical material at Radiumhemmet, Ahlborn has shown that there is a definite relation of the syndrome to cancer. The first two instances observed suggestive of such a relation concerned multiple squamous cell cancer of the cheek in women who had had Plummer-Vinson symptoms for years. It soon became quite clear that a high percentage of the women with squamous cell cancer of the mouth, pharynx and upper part of the esophagus had had anemia and dysphagia. Exact final figures are not yet available, but of ninety-four cases studied with particular reference to the Plummer-Vinson syndrome during 1931-1935 the outcome was positive in fifty-seven instances (60 per cent). The relatively greater frequency than elsewhere³ of oral and pharyngeal cancer, and especially of post-cricoid cancer, in women among the patients at Radiumhemmet is of course also significant. Ahlborn¹ states that in Radiumhemmet 90 per cent of the cases of post-cricoid cancer occurred in women and that of these women 90 per cent reported a record like that of the Plummer-Vinson syndrome. There is every reason to look forward with special interest to the results of further study. The indications are that in Sweden at least the Plummer-Vinson syndrome in women is a highly important predisposing factor to cancer in the mouth, the pharynx and the upper part of the esophagus. How is it elsewhere? It is noteworthy that there seems to have been uncovered an apparently preventable malnutritional condition that greatly favors the development of cancer. Early diagnosis of the condition with prompt and effective treatment, curative and preventive, is needed in order to forestall cancer, the foundations for which may be laid long in advance of its appearance.

CRITICAL CREOSOTE CRITERIA

A recent Report of the Council on Pharmacy and Chemistry of the American Medical Association¹ indicated that creosote and its allied preparations have received more promotion and widespread application in the past than is warranted by the available pharmacologic evidence. The Council found little published scientific evidence to substantiate claims of some drug firms for the value of these compounds in the treatment of various pulmonary conditions. Before reaching a final decision the Council sent a questionnaire to members of the Association of American Physicians and the American Pediatric Society. The result of this survey confirmed the Council's conclusions and indicated that such drugs are rarely employed by leaders in the profession and that their rationale is little understood by those who do employ them. The Council omitted all such preparations from New and Nonofficial Remedies because they are marketed without satisfactory evidence that they have sufficient therapeutic value and their use is based entirely on empiricism.

Fellows,² who previously reported three studies of a series now reports a critical study of the effect of orally administered calcium creosotate on the twenty-four hour sputum of patients with pulmonary tuberculosis. This author indicates that the purpose of his fourth investigation was to determine whether or not any modification of twenty-four hour sputum specimens could be demonstrated during a period of calcium creosotate administration. To accomplish this the author measured the volatile phenol content and the volume of these specimens in a total of fifty-six cases showing similar degrees of lung change. Approximately half of these were used as controls to compare with the patients who received the drug. In spite of the fact that estimations of the volatile phenols excreted in the urine of patients who received the highest oral doses of the drug indicated adequate absorption, significant change in either the sputum phenols or sputum volumes was not observed in any of the cases during the period of calcium creosotate administration. In one group not more than two 0.26 Gm. tablets three times a day could be given because of nausea after administration for a period of one month. In another group the majority of patients tolerated doses as high as four tablets three times a day for a period of five months.

The author emphasizes the conclusiveness of his observations because of the large doses administered to many of the patients. Significantly an equal number of patients were unable to tolerate such large doses for a shorter period, which further emphasizes the useless-

ness of the employment of such treatment in pulmonary disorders on the basis that an appreciable phenol concentration in the lungs is produced. The author's failure to find evidence of excretion of phenols in the sputum of patients who received calcium creosotate suggested the necessity of investigating expired air of animals given the drug. Observations on six rabbits revealed that phenolic material was not present in their expired air during a period of eight to eighteen hours after each animal had been given 0.5 Gm. of water-soluble calcium creosotate phenols by stomach tube.

The results of the entire study not only invalidate the reports of other workers who attempted to establish a rationale for creosote compounds in pulmonary disorders on the basis of change in the expired air during administration of such drugs but also disprove previous claims for symptomatic relief because of the increase in expectoration and appetite or lessening of cough. The author selected tuberculous patients for the study only because such cases provide a more constant daily output of sputum, whereas in most bronchial diseases the daily variation in volume of sputum is so great that it is impossible to conduct reliable control studies. The absence of adequate controls probably explains many of the statements in the literature concerning the changes in volume of sputum after creosote. Such statements appear to be the result of isolated observations on persons who might have shown the same changes without the drug.

BACTERIA, THE SMALLEST OF
LIVING THINGS

The famous paper of the plant physiologist Ferdinand Cohn entitled "Bacteria, the Smallest of Living Things" introduced scientific bacteriology; it was first published in Berlin, Germany, in 1872 and has just been issued in an English translation in the *Bulletin of the History of Medicine* and as a separate reprint.¹ Morris C. Leikind has added an informative and interesting preface. The paper was translated in 1881 by Charles S. Dolley, who, by the way, spent several years as a student in Europe, at the university in Leipzig and at the zoological station in Naples. Dolley, while yet a medical student at the University of Pennsylvania, read Cohn's paper in the original German. Recognizing at once its importance for the entire field of biology and bacteriology, he published the translation which is the basis of this new edition.

Cohn's systematic investigations of the life of the microbe world began in 1851. The basis of systematic bacteriology even today is his classification of plant micro-organisms named according to their forms: cocci, bacteria, bacilli, vibrios, spirilla and spirochetes. His discovery of spores, that form of bacteria which continues to live even after life for the bacterium proper

2. Fellows, E. J.: Studies on Calcium Creosotate: IV. Observations on Its Use in Pulmonary Tuberculosis, Am. J. M. Sc. 197:683 (May) 1939. (These studies were conducted under a grant from the Maltbie Chemical Co., Newark, N. J.)

1. Baltimore, Johns Hopkins Press, 1939.

has become impossible, is one of the most important experimental observations in the field of plant physiology.

Bacteriology cannot be regarded merely as a branch of medical science. The discovery of the pathogenic germs, chiefly due to Pasteur and Koch, was important for the science of pathology and especially for the study of infectious diseases; but the number of those bacteria which play a part as agents of diseases and have become commonly known is relatively insignificant in the total kingdom of microbes. Where there are fifty or a hundred bacterial agents of human and animal diseases there are thousands of different species in the microbe world. Great biologic importance is due to bacteria and related fungi, which play a decisive part in the decomposition of organic matter; i. e. in decay and putrefaction of dead plant and animal bodies, in fermentation and normal digestion, in the loosening of the soil, in the aggregation of nitrogen in the roots of certain plants, in the reduction of sulfur, also an indispensable element for life, and in numerous other biologic processes. Cohn's classic paper is still important today because he, "like nobody before or after him," as the present editor remarks in his preface, "has so brilliantly and clearly indicated the position of bacteria in the general economy of nature." Cohn describes the eternal circle of organic life. His essay is just as well worth reading today as when it was first published in 1872; it is not really antiquated in essentials. Thus he writes, according to his English translator (page 25 of the new edition):

The whole arrangement of nature is based on this, that the body in which life has been extinguished succumbs to dissolution in order that its material may become again serviceable to new life. If the amount of material which can be molded into living beings is limited on the earth, the same particles of material must ever be converted from dead into living bodies in an eternal circle; if the wandering of the soul be a myth, the wandering of matter is a scientific fact. If there were no bacteria, the material embodied in animals and plants of one generation would after their decease remain bound, as are the chemical combinations in the rocks; new life could not develop, because there would be a lack of body material. Since bacteria cause the dead body to come to the earth in rapid putrefaction, they alone cause the springing forth of new life and therefore make the continuance of living creatures possible. The wonderful fact that putrefaction is a work performed by bacteria does not stand alone; there is an entire series of chemical changes which are produced by bacteria and similar microscopic forms. These processes are usually designated as fermentation phenomena, and the organisms which cause the same as fermentation fungi.

Ferdinand Cohn, director of the plant-physiologic institute at the university of Breslau, aroused special interest in medical history in still another way. That was his meeting with Robert Koch. When Cohn published his paper on "Bacteria, the Smallest of Living Things," in 1872 Koch was still completely unknown. In 1876, when Koch demonstrated his discovery of the life cycle of anthrax bacilli, he was still a simple country doctor and he presented himself and his work to Cohn. From the blood of infected animals Koch had been able to grow these bacilli in pure culture and had been first

to prove experimentally the significance of anthrax spores. These resistant spores become mature bacilli. With the pure cultivated germs Koch was able to produce real anthrax or splenic fever in the bodies of susceptible animals. That important discovery was the first of Koch's great accomplishments in the etiology of infectious diseases. The memorable demonstration began on April 30, 1876, and lasted for three days. "Koch completely convinced his audience of his discovery, and Cohn's enthusiasm was boundless."

Ferdinand Cohn tried at once to remove all obstacles from Koch's way. He not only published in his own periodical (*Beiträge zur Biologie der Pflanzen*, 1876) the paper, fundamental for medical bacteriology, but also did his best to secure for Koch an adequate position in Berlin. Thus the botanist Ferdinand Cohn prepared the way for the medical man Robert Koch. The aging Virchow, then president of the Berlin Medical Society, met the young investigator and colleague with the greatest skepticism. This went so far that in 1882 Koch was not permitted to deliver before the medical society his lecture on the Etiology of Tuberculosis, a lecture which later became world famous. Ferdinand Cohn was free from the malevolent jealousy which has unfortunately played a part in scientific competition among important scholars. Cohn's own work was fundamental as the basis of scientific bacteriology. The republication of this classic paper (in the original English translation) is most commendable.

AMERICAN DOCTORS ON POSTAGE STAMPS

Last year *THE JOURNAL*¹ called attention to the disparity between the number of physicians in other countries who had been honored by special issues of postage stamps and the number so honored in the United States. Now the United States Postoffice Department announces a famous American series of postage stamps which will soon be issued. Among some thirty Americans to be thus memorialized are two physicians, Major Walter Reed of the U. S. Army Medical Corps and Dr. Crawford W. Long of Georgia. Although other names might well have been added to this brief list, no one will deny that the two selected fully merit this honor. Our Eastern shores and many of our cities were invaded some ninety-five times by yellow fever before Drs. Reed, Carroll, Agramonte and Lazear conducted experiments in Cuba which demonstrated that yellow fever is transmitted by the bites of certain species of mosquitoes. Yellow fever had been present in the Western hemisphere for at least 300 years and had caused tens of thousands of deaths. Following this discovery by Walter Reed and his associates in 1900, yellow fever soon disappeared from North America and has never returned. Dr. Crarr-

1. Medical Portraits on Stamps, J. A. M. A. 111: 536 (Aug. 6) 1914.

ford W. Long, a general practitioner of medicine, on March 30, 1842, first used sulfuric ether as an anesthetic during the performance of a surgical operation. Dr. Long performed this operation on James M. Venable in Jefferson, Jackson County, Ga., a small town then many miles from a railroad. The general practitioner of medicine and the army medical officer thus memorialized typify the benevolent character of the service which physicians give to suffering humanity.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Changes in Health Officers.—Dr. Walter J. Broad, Montgomery, has been appointed health officer of Bullock County, succeeding Dr. Hubert R. Owen, Union Springs, who resigned to do postgraduate work at the University of Pennsylvania, it is reported. Dr. Benjamin S. Black, Grove Hill, has resigned as health officer of Clarke County.

Auditorium for County Medical Society.—The Jefferson County Medical Society opened its new auditorium in the new Hillman Clinic Building, Birmingham, with a postgraduate seminar September 8-9. The auditorium has a seating capacity of 300 and has an adjoining club room. Included with the furnishings are provisions for a loud speaker, a talking moving picture machine and a stationary screen. The seminar was the first held by the county medical society and it is planned to make it an annual affair. The speakers included:

Dr. Angus M. McBryde, Durham, N. C., Recent Investigations on the Prevalence and Treatment of Undulant Fever.
Dr. Benjamin S. Barringer, New York, Malignant Conditions of the Genito-Urinary Tract.
Dr. William F. Riehoff Jr., Baltimore, Surgical Treatment of Carcinoma of the Lung.
Dr. Elmer L. Sevringhaus, Madison, Wis., Pituitary Therapy in General Practice.
Dr. Hobart A. Reimann, Philadelphia, Treatment of Pneumonia.
Dr. Eugene F. Traub, New York, Dermatomyiasis.

CALIFORNIA

Society News.—At a meeting of the Los Angeles Society Neurology and Psychiatry October 18 the speakers were Emil Seletz on "Brain Tumor with Abdominal Symptoms"; David L. Reeves, "Epidural Hemangioma Associated Hemangioma of the Vertebra," and Cyril B. Courville, "Genesis and Pathology of Intracranial Aneurysm." The Surgical Treatment of Pulmonary Tuberculosis "Limitations of the Trudeau Society in Los Angeles October 24.

Personal.—Dr. Walter Rapaport, Imola, has been appointed superintendent of the Mendocino State Hospital, Talmadge, succeeding Dr. Ruggles A. Cushman, who resigned October 1. Col. James A. Mattison, for sixteen years chief medical officer in charge of the Veterans Administration Facility, West Los Angeles, has announced his retirement, it is reported. A reception was held prior to departure to his ranch in Glendora. Dr. William J. Quinn has resigned as health officer of Eureka to accept a similar position with Humboldt County.

COLORADO

State Medical Election.—Dr. William H. Halley, Denver, was chosen president-elect of the Colorado State Medical Society at its annual convention in Colorado Springs October 7 and Dr. John W. Ames, Denver, was installed as president. Dr. Carl W. Maynard, Pueblo, was elected vice president. The 1940 meeting will be held in Glenwood Springs. At the recent session it was decided to appoint a committee on milk control to carry on a campaign for uniform milk regulations in all Colorado communities.

Resolution Adopted by State Examiners.—The state board of medical examiners adopted a resolution October 3 making a physician ineligible for licensure in Colorado who attempts the practice of medicine in the state, either alone or

through association with a licensed physician, without first obtaining a license. The resolution reads as follows:

Any physician who attempts to practice medicine in the State of Colorado, either alone or through association with a licensed physician, without first having obtained a license from the state board of medical examiners shall be considered to have violated the provisions of Section 17, Chapter 109, Colorado Statutes Annotated 1935, and he shall not be considered eligible subsequently to appear as an applicant for medical licensure.

CONNECTICUT

Personal.—Dr. Joseph I. Linde, New Haven, has been appointed a member of the state tuberculosis commission to serve the unexpired term of the late Dr. Stephen J. Maher.

Hospital News.—The Dillon Memorial Building, a new unit of the St. Francis Hospital, Hartford, was recently dedicated by Miss Catherine Dillon, Hartford, was recently dedicated by her brothers, Edward and Charles.

Medical History Library.—The establishment in the Yale University School of Medicine, New Haven, of a library devoted to the history of medicine has been announced. Collections of Dr. John F. Fulton and of the late Dr. Harvey Cushing, both of the Yale faculty, will serve as a nucleus of the library, and Dr. Arnold C. Klebs, Les Terrasses, Nyon, Switzerland, has announced that he is devoting to Yale his library on the history of science and of medicine, including his apparatus for the study of early texts. To house the collection be extended by the use of funds set aside by the Yale Corporation from the estate of John W. Sterling. The extension will be Y shaped with accommodations for 400,000 volumes. In one prong of the Y will be the historical collections, in the other a working library for the school. Construction will begin within the near future, it was stated.

DELAWARE

State Medical Election.—Dr. Bruce Barnes, Seaford, was chosen president-elect of the Medical Society of Delaware at its annual session in October. Dr. Meredith I. Samuel, Wilmington, will take office as president in January. Dr. John H. Mullin, Wilmington, is secretary. Rehoboth Beach was designated as the place for the 1940 meeting, the time to be determined later.

GEORGIA

Society News.—The Georgia section of the Southeastern Surgical Congress and the Seventh District Medical Society held a joint session at the Coosa Country Club, Rome, October 4.—Dr. Stephen T. Brown, Atlanta, among others, discussed "Tuberculosis of the Bladder" before the Fulton County Medical Society, Atlanta, October 19.

Changes in Health Officers.—The state department of health announces the following changes in health officers:

Dr. James H. Litton, Carbon, W. Va., succeeding Dr. Stuart P. Vandivier, Milledgeville, as commissioner of health for Baldwin County, August 26.
Dr. George M. Anderson, Morgan, succeeding Dr. Luther A. Brendle, Eastman, as commissioner of health for Dodge County, September 6.
Dr. Vandivier succeeding Dr. William F. Castellow, Americus, as commissioner of health for Sumter County, September 1.
Dr. Oliver W. Jenkins, Edison, succeeding Dr. Clair A. Henderson, Dawson, of Terrell County.
Dr. Albert G. LeRoy, Lyons, has resigned as health commissioner of Toombs County, effective September 25, to accept a similar position succeeding Dr. Robert H. Haralson Jr., Tifton, in Tift County. The latter plans to engage in private practice in Calderwood, Tenn.

District Meeting.—The Fifth District Medical Society was addressed at the Academy of Medicine, Atlanta, October 5 by the following, among others:

Dr. Clarence O. Sappington, Chicago, The Etiologic, Diagnostic and Medicolegal Problems of Occupational Diseases.
Dr. George H. Semken, New York, The Practitioner and the Cancer Problem.
Dr. Ray M. Balyeat, Oklahoma City, Diagnosis and Treatment of Common Allergic Manifestations Encountered by the General Practitioner.

Dr. Edgar Hill Greene, president of the Fulton County Medical Society, gave the address of welcome.

ILLINOIS

Personal.—Dr. Henry B. Knowles, assistant managing officer of the Peoria State Hospital, has been appointed acting managing officer of the Anna State Hospital, succeeding Dr. Andrew F. Barnett, resigned.—Dr. Paul H. Harmon, Springfield, has resigned as superintendent of the division of handicapped children in the state department of welfare to engage in private practice in Fresno, Calif.

Society News.—Dr. Italo F. Volini, Chicago, discussed "Sulfapyridine Treatment of Pneumonia" before the Ogle County Medical Society October 26.—At a meeting of the LaSalle County Medical Society at Starved Rock October 26 Dr. Lowell D. Snorf, Chicago, spoke on "Functional Disorders of the Stomach and Intestines."—Dr. Jesshill Love, Louisville, Ky., addressed the St. Clair County Medical Society October 5 in East St. Louis on "X-Ray in Treatment of Skin Malignancies."

Chicago

Dr. Kronfeld to Direct Postgraduate Education.—Dr. Peter Kronfeld, professor of ophthalmology at Peiping Union Medical College, Peiping, China, for the past six years, has been appointed dean of instruction at the Illinois Eye and Ear Infirmary. This is a new position, in which Dr. Kronfeld will supervise instruction of interns and residents and will have charge of short courses to be given at various times at the infirmary. Dr. Kronfeld, who graduated from the University of Vienna Faculty of Medicine in 1923, came to Chicago in 1928 as assistant professor of ophthalmology at the University of Chicago. In 1929 he became associate professor and remained on the faculty until he went to Peiping in 1933.

Dr. Post Made Dean of Rush Graduate School.—Dr. Wilber E. Post, clinical professor of medicine at Rush Medical College and president of the staff of Presbyterian Hospital, has been appointed dean of Rush Graduate School of Medicine. Organization of the new program of graduate work to become effective in 1942 (*THE JOURNAL*, October 14, p. 1498) will now begin under Dr. Post's direction. Dr. Post was born in Lowell, Mich., in 1877 and graduated at Rush Medical College in 1903, joining the faculty two years later. He has served as clinical professor of medicine since 1916. He has also been a member of the board of trustees of the University of Chicago since 1919, but under the practice of the board his acceptance of the administrative position required his resignation as trustee.

IOWA

Dr. Geiling Gives Rockwood Lecture.—Dr. Eugene M. K. Geiling, professor of pharmacology, Division of Biological Sciences, University of Chicago, will deliver the third annual Paul Reed Rockwood lecture at the State University of Iowa College of Medicine, Iowa City, November 15. His subject will be "Comparative Anatomy and Pharmacology of the Pituitary Gland."

Society News.—Dr. Leo H. LaDage, Davenport, discussed "Plastic Procedures in General Practice" before the Bremer County Medical Society in Waverly September 27.—At a meeting of the Cass County Medical Society in Atlantic September 21 Dr. Walter A. Anneberg, Carroll, spoke on "Treatment of Pneumonia with Sulfapyridine."—At a meeting of the Lee County Medical Society in Keokuk October 20 the speakers were Drs. John I. Brewer on "Uterine Bleeding"; Grant H. Laing, "Clinical Importance of Pylorospasm"; George W. Hall, "Newer Treatment of Mental and Nervous Diseases," and Fremont A. Chandler, "Low Back Pain." All are from Chicago.

Postgraduate Courses.—Postgraduate extension courses are now under way in the first, second, third, fourth and tenth districts of the state. Participating in these courses as instructors are:

- Dr. Fred M. Smith, Iowa City, Diagnosis and Treatment of Coronary Thrombosis.
- Dr. Willis M. Fowler, Iowa City, The Anemias.
- Dr. John H. Peck, Oakdale, Pulmonary Tuberculosis.
- Dr. Nathaniel G. Alcock, Iowa City, Management of Common Urinary Disorders.
- Dr. William F. Mengert, Iowa City, Common Gynecologic Disorders.
- Dr. Donald C. Conzett, Dubuque, Minor Surgery.
- Dr. Arnold S. Jackson, Madison, Wis., The Acute Abdomen.
- Dr. Everett D. Plass, Iowa City, Treatment of Leukorrhea.
- Dr. Adolph L. Saks, Iowa City, Diagnosis and Treatment of Neurosis.
- Dr. Daniel L. Sexton, St. Louis, Endocrine Therapy: Its Application in General Practice.
- Dr. Fremont A. Chandler, Chicago, Basic Problems in the Management of Fractures.
- Dr. Roger L. J. Kennedy, Rochester, Minn., Gastrointestinal Disturbances in Infants and Children; Convulsive Attacks in Infants and Children.
- Dr. William D. Paul, Iowa City, Hypertension with Complicated Heart Lesions.
- Dr. Lester R. Dragstedt, Chicago, Endocrinology.
- Dr. Henry W. F. Woltman, Rochester, Minn., Neuritis.
- Dr. Edwin B. Winnett, Des Moines, Management of Diabetics.
- Dr. Leon S. McGoggan, Omaha, Common Obstetric Abnormalities.
- Dr. Lewis M. Overton, Des Moines, Backache.
- Dr. Edgar V. Allen, Rochester, Minn., Hypertension.
- Dr. Ernest Kelley, Omaha, The More Common Neurologic Conditions.
- Dr. Edwin L. Miller, Kansas City, Mo., How Can We Reduce the Mortality Rate of Acute Appendicitis?

KANSAS

Society News.—The Sedgwick County Medical Society was addressed in Wichita October 3 by Dr. Paul F. Stookey, Kansas City, Mo., on "Staphylococcic Septicemia" and October 17 by Drs. Albert R. Hatcher, Wellington, and Hervey R. Hodson, Wichita, on "Problems in the Management of Carcinoma of the Breast" and "Peritonitis" respectively.—At a meeting of the Cowley County Medical Society in Arkansas City September 28 the speakers were Drs. James S. Hibbard and Vincent L. Scott, Wichita, on "Diagnosis and Treatment of Intestinal Obstructions" and "Convulsions in Infancy and Childhood."—The Northwest Kansas Medical Society was addressed at Norton October 3 by Drs. Daniel V. Conwell, Halstead, on "Migraine"; Lloyd O. E. Peckenschneider, Halstead, "Treatment of Congestive Heart Failure," and James L. Jenson, Colby, "Basal Metabolism."

KENTUCKY

Changes in Health Officers.—Dr. Elmer R. Schnake, Newport, has been appointed health officer of that city.—Dr. George B. Davis, Guilford, Conn., succeeds Dr. Chester R. Markwood, Glasgow, as health officer of Barren County.—Dr. Reuben M. Coblin, Frankfort, has been appointed health officer of Franklin County to succeed the late Dr. Eugen C. Roemele.—Dr. James W. Miller, Greensburg, has resigned as director of the Green County Medical Society to enter private practice.

Society News.—Drs. William W. Nicholson and Harry S. Andrews addressed the Jefferson County Medical Society, Louisville, October 2 on "Sulfapyridine in the Treatment of Pneumonia in Children" and "Acute Pharyngolaryngotracheobronchitis in Children" respectively.—Drs. Carl H. Fortune and David Woolfolk Barrow, Lexington, addressed the Bourbon County Medical Society, Paris, October 19 on "Pituitary Functions" and "Surgical Treatment of Varicose Veins" respectively.—Drs. Catherine Brummett and Albert W. Cowan, Middlesboro, addressed the Bell County Medical Society, Middlesboro, October 13 on "Nutritional Requirements of the Normal Infant" and "The Climacteric and the Use of the Estrogenic Hormone" respectively.

District Meetings.—The sixth and seventh councilor districts of the Kentucky State Medical Association held a joint meeting in Somerset October 26. A symposium on a proposed law to require premarital medical examinations was presented in the afternoon by Dr. Fred W. Caudill, Louisville, and Nicholas W. Klein, Somerset attorney. Speakers on the scientific program were Drs. Harry S. Andrews, Louisville, on "Vitamin Deficiency Diseases of Children"; Arthur B. Barrett, Lexington, "Leukorrhea: Its Differential Diagnosis and Treatment," and John Harvey, Lexington, "Sulfapyridine in the Treatment of Pneumonia."—The Third District Medical Society met with the Christian County Medical Society at Hopkinsville October 17, with the following speakers: Drs. John W. Scott, Lexington, "The Problems of the Neuroses"; John M. Coffman, Owensboro, "Recent Advances in Neuropsychiatry," and Addie M. Lyon, Hopkinsville, superintendent of the Western State Hospital, on the work of the hospital.

MASSACHUSETTS

Annual Meeting on Mental Hygiene.—The Massachusetts Society for Mental Hygiene will hold its annual convention at the Twentieth Century Club, Boston, November 23. The principal speaker will be Dr. George S. Stevenson, New York, medical director of the National Committee for Mental Hygiene, who will discuss "New Vistas for Mental Hygiene."

Society News.—At a meeting of the Harvard Medical Society October 10 Dr. Mercier Fauteux, Montreal, Canada, spoke on "A New Surgical Method to Improve the Blood Supply to the Heart in Coronary Disease."—The Suffolk District Medical Society was addressed in Boston October 25 by Dr. Charles H. Lawrence, Dr. Joseph T. Smith and Nicholas T. Werthessen on "Obesity and Menstrual Disturbance: Endocrine and Endometrial Studies"; Drs. Richard H. Overholt, "Clinical Studies in Primary Malignancy of the Lung"; Siegfried J. Thannhauser, "Xanthomatosis"; Samuel Proger, "Observations on Heart Disease," and Joseph H. Pratt, "Secretin Test of Pancreatic Function."—A symposium on "Pain: Its Significance in Diagnosis and Prognosis" was presented October 10 before the Four County Medical Society, comprising the county societies of Berkshire, Franklin, Hampden and Hampshire, by Drs. Lewis M. Hurxthal, Arthur W. Allen, Joc V. Meigs, Boston, and Foster Kennedy, New York.

MICHIGAN

Society News.—Dr. Stanley Milton Goldhamer, Ann Arbor, discussed "Transfusion and the Blood Bank" before the Washtenaw County Medical Society October 16.—The West Side Medical Society, Detroit, was addressed recently by Dr. John G. Mateer, among others, on "Evolution of Knowledge Regarding Vitamin K and Blood Prothrombin in Relation to Hemorrhage."—At a meeting of the Wayne County Medical Society, Detroit, October 16 Dr. Russell L. Haden, Cleveland, spoke on "Etiology and Diagnosis of Leukemia."—Dr. Harry Bakwin, New York, discussed "Newer Developments in Vitamins" before the Calhoun County Medical Society in Battle Creek October 3.—Dr. Manuel E. Lichtenstein, Chicago, addressed the Van Buren County Medical Society, South Haven, October 10 on "Periapical Phlegmon and Abscess."

NEW JERSEY

State Society Arranges Medical Care for Needy.—The Medical Society of New Jersey has issued for the second year its invitation to any person in the state in need of medical care to communicate with the executive office in Trenton. All requests will be referred to the county medical societies of the counties from which the requests come. The societies will assign physicians to investigate applications and provide care in all cases of genuine need.

Dr. Flexner Retires.—Abraham Flexner, LL.D., director of the Institute for Advanced Study, Princeton, since its establishment in 1930, has resigned on the advice of his physician. Dr. Flexner, now 72 years old, has been prominent in education for many years. He was associated with the Carnegie Foundation for the Advancement of Teaching from 1908 to 1925, serving as secretary the last eight years. Early in this period he made the well known study of medical education at the invitation of the Council on Medical Education of the American Medical Association, which led to basic reforms in the medical schools of the country. The study was published in 1910. From 1925 to 1928 he was director of the division of studies and medical education of the General Education Board. He holds many honorary degrees, among them medical degrees from the universities of Berlin and Brussels. His successor at the Institute for Advanced Study will be Frank Aydelotte, LL.D., president of Swarthmore College, Swarthmore, Pa., since 1921.

NEW YORK

Hospital News.—A new \$100,000 wing was opened at the Buffalo Columbus Hospital, Buffalo, October 23. The new unit now forms the central part of the hospital. It contains three operating rooms, accommodations for twenty private and ten semiprivate patients, and enlarged outpatient quarters in the basement. This is the seventh major addition to the hospital since it was founded in 1908 by Dr. Charles R. Borzilleri.

Project to Discover Hard-of-Hearing Children.—The New York State Commission to Study Facilities for the Care of the Deaf and the Hard of Hearing announces a case-finding project to discover children under 6 years old who have defective hearing. The project will be carried out in Columbia County under the direction of Dr. Marion F. Loew, a member of the staff of the state department of health and of the commission, in cooperation with the county health commissioner, Dr. Louis Van Hoesen, Hudson, and with the health department's divisions of maternity, infancy and child hygiene and communicable diseases.

New York City

Personal.—Dr. Condict W. Cutler Jr. has been elected an alumni trustee of Columbia University, succeeding Dr. Eugene H. Pool.—Dr. John Francis McGrath has been appointed director of gynecology and obstetrics at St. Vincent's Hospital.

Lectures on Venereal Diseases.—The bureau of social hygiene of the department of health has opened its fall program of lectures on venereal disease for physicians and the public. Sessions for physicians are being held Saturday mornings from October 14 to November 26. In addition, an evening meeting was held October 31 and another is scheduled for December 6. Meetings for the public were announced for October 18, November 15 and December 20. In cooperation with this program the section of historical and cultural medicine of the New York Academy of Medicine presented a symposium on syphilis November 8 by Drs. John L. Rice, health commissioner, Herman Goodman and Theodore Rosenthal.

Society News.—Drs. Harry Gold, New York, and Robert Edward Gross, Boston, addressed the New York Heart Association at a scientific session, November 7 on "Studies on the Nature of Digitalis Action" and "Experiences with Surgical Treatment of the Patent Ductus Arteriosus" respectively.—Drs. Francis W. Sovak, New York, and Abraham Shulman, Paterson, N. J., addressed the Bronx Gynecological and Obstetrical Society October 23 on "Operative Treatment of Sterility" and "Pregnancy Following Tubal Implantation" respectively.—Carl R. Moore, Ph.D., Chicago, and Philip E. Smith, Ph.D., addressed the New York Academy of Medicine at its stated meeting November 2 on "Physiology of the Testes and Therapeutic Application of Male Sex Hormones" and "Physiology of the Ovaries" respectively.—Dr. James W. Smith has been elected president of the Alumni Association of the New York University College of Medicine; Drs. Luther B. MacKenzie, vice president, and Phineas Bernstein, secretary.

NORTH CAROLINA

Annual Symposium at Duke.—The sixth annual symposium conducted by Duke University School of Medicine, Durham, October 19-21 was on "Diseases of the Lungs and Thorax." The visiting speakers included Drs. Edward D. Churchill, Maxwell Finland and Frederick T. Lord, Boston; Daniel M. Brumfiel, Saranac Lake, N. Y.; Chester A. Stewart, Minneapolis; Harry A. Bray, Ray Brook, N. Y.; Cameron Haight, Ann Arbor, Mich.; William D. Andrus and Dickinson W. Richards Jr., New York; Isaac A. Bigger, Richmond, Va.; Charles R. Austrian and William F. Riehoff Jr., Baltimore; Stuart W. Harrington, Rochester, Minn.; Daniel C. Elkin, Atlanta, Ga., and Gabriel Tucker, Philadelphia.

Society News.—Dr. Bernard J. Alpers, Philadelphia, gave two lectures before the Guilford and Forsyth county medical societies in Greensboro in September as the first of a series of seminars sponsored by the two societies. His subjects were "Interpretation of Neurologic Signs in Common Neurologic Disorders" and "Diagnosis and Treatment of Common Neurologic Disorders."—Drs. Joseph T. Sullivan and Thomas R. Huffins addressed the Buncombe County Medical Society, Asheville, October 16 on "Traumatic Rupture of Liver and Diaphragm" and "Urologic Anomalies" respectively.—Dr. Hubert B. Haywood, Raleigh, addressed the Hartnett County Medical Society, Dunn, recently on "Medicine at the Crossroads."

OHIO

Personal.—Dr. George Frederick Moench, Mount Victory, has been appointed health officer of Delaware and Delaware County.—Dr. Orlando E. Harvey, superintendent of the District Tuberculosis Hospital, Lima, has resigned, it is reported, and Dr. Edward W. Laboe, Howell, Mich., has been named to succeed him.—Dr. Maurice Lincoln Fisher, Mansfield, has been appointed medical director of tuberculosis work in Richland County. A half mill tax levy to provide funds for the care of indigent tuberculosis patients will become available in January.

Society News.—Dr. Louis H. Newburgh, Ann Arbor, Mich., addressed the Mahoning County Medical Society, Youngstown, October 17 on metabolism. Dr. Jerome Selinger, New York, will speak November 21 on peptic ulcer.—Drs. Raymond S. Rosedale, Canton, and Walter K. Stewart, Youngstown, addressed the Stark County Medical Society at Canton September 21 on "Infections of the Neck" and "Progress in Medical Economics During the Past Year" respectively.—Dr. Camille J. DeLor, Columbus, addressed the Fayette County Medical Society in Washington Court House recently on "Bile Salts in the Treatment of Biliary Diseases."—Dr. Lauren N. Lindenberger, Troy, addressed the Miami County Medical Society, Piqua, recently on "Dermatitis Resulting from Sensitivity to Novocain."—At a meeting of the Marion Academy of Medicine recently the speaker was Dr. Russel G. Means, Columbus, on "New Conceptions of Otitis Media."—Dr. John A. Toomey, Cleveland, addressed the Montgomery County Medical Society, Dayton, October 20 on "Differential Diagnosis of Various Forms of Meningeal Irritations."

OKLAHOMA

Another Medical Supplement.—A twenty-four page medical section in tabloid form was published September 24 by *The Daily Oklahoman*, Oklahoma City, under the supervision of the Oklahoma County Medical Association. Articles of a general medical and health nature carried by-lines, whereas those dealing with specific diseases and therapeutic methods carried merely the by-line "By a Member, Oklahoma County Medical Association."

MEDICAL NEWS

JOUR. A. M. A.
Nov. 14, 1939

Personal.—Dr. William C. Tisdal, medical superintendent of the Western Oklahoma Tuberculosis Sanatorium, Clinton, has resigned to resume private practice, it is reported. Dr. Richard M. Adams, health officer of Ada and Pontotoc County, has been appointed health officer of Tulsa. Dr. Adams joined the state board of health in 1935 and has served in various capacities. Dr. Solomon P. Roberts, Nowata, has been appointed health officer of Nowata County.

Society News.—Dr. Edward N. Smith, Oklahoma City, addressed the Garfield County Medical Society, Enid, September 28 on "Care of the Newborn Infant." Dr. David V. Hudson, Tulsa, addressed the Tulsa County Medical Society, Tulsa, October 23 on "The Epidemiology of Venereal Disease." Dr. David W. Gillick addressed the Pottawatomie County Medical Society, Shawnee, October 21 on "Collapse Therapy in the Treatment of Pulmonary Tuberculosis." Dr. George H. Kimball, Oklahoma City, discussed plastic surgery at a meeting of the Woods County Medical Society, Altus, September 25.

OREGON

State Tuberculosis Hospital Dedicated.—The University State Tuberculosis Hospital in Sam Jackson Park, Portland, was dedicated November 1 under the auspices of the state board of control and the state board of higher education with the Oregon Tuberculosis Association cooperating. This is the third unit of Oregon's program of state tuberculosis hospitals and has a capacity of eighty beds. The cost of construction was \$290,909. It will be maintained as a unit of the hospitals and clinics of the University of Oregon Medical School under the direction of Dr. David W. E. Baird Jr., medical director, and Ralf Couch, general superintendent. The major function of the hospital will be to provide surgical treatment for tuberculosis, but an outpatient service will also be maintained.

PENNSYLVANIA

Sixth Institute on Exceptional Child.—The Child Research Clinic of the Woods Schools, Langhorne, held its sixth institute on the exceptional child October 24. The general topic of discussion was "Progress of Scientific Research in the Field of the Exceptional Child," and the speakers included Dr. Russell S. Boles, Philadelphia, who presided at one session; William E. Blatz, Ph.D., director, Institute of Child Study, University of Toronto, Canada, on "What Is an Exceptional Child?" and Dr. Juliette Louise Despert, New York, "Research in the Nursery School."

Philadelphia

Second de Schweinitz Lecture.—Dr. Walter R. Parker, Detroit, will deliver the second de Schweinitz Lecture before the section on ophthalmology of the College of Physicians of Philadelphia November 16. His subject will be "Uveitis with Associated Alopecia Poliosis, Vitiligo and Deafness."

TENNESSEE

Personal.—Dr. Jewell R. Wilson has resigned as superintendent of the Western State Hospital, it is reported. Dr. James E. Dedman, manager of the Veterans Administration Facility, Memphis, has gone on leave of absence and will retire from the service Jan. 31, 1940, when he will have reached the retirement age, it is reported. He has been succeeded at Memphis by Dr. Horace C. Dodge, recently at Fort Bayard, N. M.

Society News.—Dr. Elkin L. Rippey addressed the Nashville Academy of Medicine and Davidson County Medical Society September 19 on "Incidence and Complication of Gastric Ulcer." Drs. Thomas C. Moss and William M. Adams, Jackson, September 25 on "Undulant Fever" and "Indications and Time for Plastic Surgery," respectively. Dr. John G. Fleming, Cincinnati, was the banquet speaker at a meeting of the East Tennessee Medical Association in Greenville October 3. His subject was "Abruptio Placentae." Dr. Cobb Pilcher, Nashville, spoke on "Modern Problems of Neurosurgery." Dr. James B. Black, Murfreesboro, was elected president of the Tennessee Public Health Association at the annual meeting in Nashville October 4.

TEXAS

District Meeting.—The Northwest Texas District Medical Society met at Mineral Wells recently. Guest speakers were Dr. Clifford J. Barborka, Chicago, who presented a paper on "Recent Advances in Nutrition," and Dr. Morton J. Tendler, Memphis, Tenn., a paper prepared by Dr. John L. McGehee, Appendicitis (Appendiceal Peritonitis).

Society News.—Drs. Nathan C. Carpenter and Jack M. Furman, Fort Worth, addressed the Tarrant County Medical Society, Fort Worth, recently on "Treatment of Acute Sprains with Procaine Hydrochloride" and "Management of Gastro-Enteric Hemorrhage" respectively. At a meeting of the Dallas County Medical Society October 12 the speakers were Drs. Cleve C. Nash, on "Surgical Treatment of Hypertension"; Horace E. Duncan, "Rural Sewage Disposal," and G. L. Hacker, "Dental Caries in Children."

Postgraduate Clinic in Fort Worth.—The Tarrant County Medical Society sponsored a medical and surgical clinic in Fort Worth September 26. The speakers were Drs. Warfield M. Firor, associate professor of surgery, Johns Hopkins University School of Medicine, Baltimore; John Zahorsky, professor of pediatrics, St. Louis University School of Medicine; George R. Herrmann, professor of clinical medicine, University of Texas School of Medicine, Galveston, and Meyer Wiener, professor of clinical ophthalmology, Washington University School of Medicine, St. Louis. At the banquet Dr. Edward H. Cary, Dallas, gave an address on socialized medicine.

VERMONT

State Medical Meeting and Election.—The annual meeting of the Vermont State Medical Society, marking the society's one hundred and twenty-fifth anniversary, was held in Burlington October 5-6 under the presidency of Dr. Edwin A. Hyatt, St. Albans. The program included the following addresses: Dr. Angus C. Black, Brattleboro, Urinary Calculi (the vice president's address); Dr. David M. Bosworth, New York, The Damaged Shoulder; Dr. David F. Erdmann, New York, Tumors of the Breast; Dr. Edward W. Archibald, Montreal, Canada, Personal Experiences in the Surgical Treatment of Appendicitis; Dr. Wilhelm Raab, Burlington, Arterial Hypertension of Cerebral Origin; Dr. Nathan B. Van Etten, New York, President-Elect of the American Medical Association, The Quality of Medicine.

A symposium on obstetrics, arranged by Dr. Herbert A. Durfee, Burlington, was presented by Drs. Claud E. Heaton and James P. Marr, New York, and Benjamin F. Clark, St. Johnsbury. Dr. Van Etten was the principal speaker at the annual banquet. Dr. Albert M. Cram, Bridgewater, was chosen president-elect; Dr. Clarence F. Ball, Rutland, was installed as president, and Dr. Benjamin F. Cook, Rutland, was reelected secretary. Next year's meeting will be in Rutland.

WEST VIRGINIA

State Societies to Meet Jointly.—The house of delegates of the Medical Society of Virginia has accepted an invitation from the West Virginia State Medical Association to meet jointly at White Sulphur Springs in 1940.

Society News.—Dr. John O. Rankin, Wheeling, addressed the Central West Virginia Medical Society at Webster Springs recently on "Intra-Articular or Joint Fractures." Dr. Temple S. Fay, Philadelphia, addressed the Ohio County Medical Society, Wheeling, October 6 on "Fundamental Basis of Attack Upon Five Problems in Medicine." Dr. William James Gardner, Cleveland, addressed the society October 20 on "Intracranial Complications of Upper Respiratory Infections."

WISCONSIN

Libraries Merged.—The Milwaukee Academy of Medicine and the Marquette University School of Medicine have consolidated their medical libraries, forming a collection of 34,000 volumes. Dr. Irving S. Cutter, dean of Northwestern University Medical School, Chicago, was the speaker at a ceremony inaugurating the new library October 17. Facilities have been enlarged at the university to receive the academy's library. Dr. Horace Manchester Brown. Henceforth the academy of medicine will hold its meetings at Marquette.

Society News.—Dr. Robert E. McDonald, Milwaukee, addressed the Dodge County Medical Society, Beaver Dam, September 28 on "Toxemias of Late Pregnancy." Drs. Harold E. Marsh and Luther E. Holmgren, Madison, addressed the Oneida-Vilas County Medical Society, Rhineland, September 20 on "Modern Treatment of Pneumonia" and "Transfusion" respectively. Drs. Lowell D. Snorf, Evanston, Ill., and Harry M. Weber, Rochester, Minn., addressed the Rock County Medical Society, Beloit, September 26 on "Functional Disorders of the Gastro-Intestinal Tract" and "Use of X-Ray in Diagnosis of Intestinal Lesions" respectively. A symposium on goiter was presented before the Milwaukee Society of Clinical Surgery October 24 by Drs. Francis D. Murphy, Frederick A. Stratton, Hobart K. B. Allebach and Hans W. Hefke.

FOREIGN

League Against Rheumatism Suspends Activities.—The International League Against Rheumatism announces from its headquarters in Amsterdam that the condition of war prevents continuation of its activities. The bureau is to be closed and all members and officials have been officially discharged from their rights and duties.

Nobel Prize for 1938 Awarded to Dr. Heymans.—Dr. Corneille Heymans, professor of pharmacology and pharmacodynamics at the University of Ghent, Belgium, received the Nobel Prize in physiology and medicine for 1938, awarded at the same time that the 1939 prize went to Dr. Gerhard Domagk of Wuppertal, Germany, who was the discoverer of the curative effects of prontosil (now neoprontosil). Professor Heymans was born in Ghent and took his medical degree at the university in 1920. He joined the research staff of the university after his graduation and became a full professor in 1929. He is also director of the J. F. Heymans Institute of Pharmacology and Therapeutics, continuing the work of his father on the influence of the Arctic regions on respiration, according to an Associated Press dispatch. Dr. Heymans has visited the United States various times, first under research fellowships and in 1929 as a delegate to the International Physiological Congress. In 1934 he delivered the Herter Lectures at New York University and in 1937 the Dunham Lectures at Harvard Medical School.

Government Services

Medical Mission to China

The U. S. Public Health Service at the invitation of the Chinese government has sent three officers to Southwestern China to investigate in cooperation with the Chinese health service the reported occurrence of a malignant disease near the Burma border and determine the menace to the United States incident to its possible spread to Oriental seaports. The officers are Drs. Louis L. Williams Jr. and Hiram J. Bush and Bruce Mayne, Dr.P.H. In addition to determining the nature and extent of the disease or diseases prevalent in the areas they visit, they will inform the Chinese authorities of the results of their survey and advise them as to control measures.

Syphilis Clinics on Wheels

"Clinics on wheels" for treatment of syphilis in four southern areas have recently been provided by the U. S. Public Health Service with funds made available by the Venereal Disease Control Act of 1938. Successful use of a "trailer clinic" in Glynn, Camden and McIntosh counties in Georgia in 1937 led to the development of the traveling clinics. In a second project in North Carolina in 1938 a specially constructed bus was found more satisfactory than a trailer. The new units are all-steel buses finished in black and silver. The interior is divided into sections, one for blood testing and injection of neoarsphenamine and the other for physical examination and administration of bismuth. There are doors on each side of the body. Two gas sterilizers are part of the equipment and there is desk space for the physician and nurse. The new buses will be used in Macon County, Ala.; Phillips and Lee counties, Ark.; Scott County, Mo., and Charleston County, S. C.

Health Service Engineer Retires

Joseph Augustin LePrince, senior sanitary engineer, U. S. Public Health Service, retired September 1 at the legal age limit after twenty-five years of continuous service. Born in England in 1875, Mr. LePrince graduated in civil engineering from Columbia University, New York, and in 1901-1902 he was assistant to Dr. William C. Gorgas, then chief sanitary officer of Havana, Cuba, during the first organized campaign for the eradication of yellow fever and malaria. From 1904 to 1914 he served as health officer of the section taken over by the United States in connection with the construction of the Panama Canal. In March 1914 he was transferred from the Isthmian Canal Commission to the public health service and was attached to the scientific research division until his retirement. During his service he engaged in studies of malaria control and in control projects, demonstrations and investigations. During 1922 he was temporarily assigned to yellow fever control measures along the Mexican border. Since March 1935 he had been consultant in malaria control to the Tennessee Valley Authority. He had been stationed at Memphis, Tenn., for several years.

The Certification of Deaths During the War

In ordinary conditions of civil life all deaths from violence have to be reported to the coroner, who holds an inquest. The uselessness as well as the difficulty of this procedure for the numerous deaths expected from air raids is evident. Like every other contingency which may arise from the war, this one has been provided for. Special arrangements have been made for the certification of deaths due to war operations. Bodies not claimed by relatives will be taken to mortuaries, which have been prepared, and the clerk to the local council will send to the registrar of deaths a certificate that the death was due to war operations. In the case of serving soldiers or airmen and of certain classes of civilians employed with the armed forces, commanding officers are authorized to issue a certificate. The ordinary procedure will apply to other deaths. A physician who attended a person prior to death should issue an ordinary death certificate and should add the words "war operations" to the particulars of violence. When no physician has been in attendance before death the relatives may request one to inspect the body and issue a certificate, and if he is satisfied that death was due to war operations he may say so. Whether a physician has been in attendance or not, there will be no necessity (as there normally is) to report these deaths to the coroner, and no inquests will be held on them.

Chaoul Therapy in England

In a short distance, low voltage form of roentgen therapy, introduced by Henri Chaoul, of Berlin (*Strahlentherapie* 53:202 [June 29] 1935), and called after him, the tube is so constructed that the anode can be brought within a few centimeters of the lesion and thus their radiation of the tissues is confined to a small area. A tube with the anode at one end for introduction into the vagina in the treatment of carcinoma of the cervix was previously introduced by Schaefer and Witte (*ibid.* 44:283 [June 15] 1932) but Chaoul is chiefly responsible for the development of this procedure for the treatment of carcinoma on the surface of the body. At the Royal Cancer Hospital, London, Chaoul therapy was first used in England in 1935 and in the ensuing years the staff has collaborated in giving it a thorough test. A report on the treatment of 500 cases treated from July 1935 to August 1938 has been published by Flood, Smithers and R. Waldron under the title "Short Distance, Low Voltage X-Ray Therapy" (*Brit. J. Radiol.* 12:426 [July] 1939). The malignant cases included 100 epitheliomas, 100 carcinomas of the breast, chiefly cutaneous recurrences, eighty-two rodent ulcers, seven carcinomas of the rectum, seven malignant melanomas, three carcinomas of the parotid gland and eleven miscellaneous cases. The nonmalignant cases included seventy-nine warts and papillomas, twenty-four pitch warts, ten keloid scars, eleven cases of leukoplakia, eleven nevi, thirteen pigmented moles, nine corns, three cases of lupus, two cases of neurofibromatosis and twenty-five miscellaneous cases.

Encouraging results were obtained in certain cases of epithelioma of the lip, scalp, face, neck, trunk, limbs and mouth, and they were remarkably good cosmetically. In rodent ulcer the results were excellent and when the eyelid was affected the majority of cases could be treated without damage to the eyeball (always a difficulty), which is protected by a contact lens with its outer surface covered with lead introduced under the lids. A recent advance is the adaptation of Chaoul therapy to carcinoma in other situations than the surface of the body. Several cases of carcinoma of the urinary bladder have been

treated by the introduction of the Chaoul tube through a suprapubic cystostomy. One massive dose is given and the wound is closed. The nonmalignant lesions, such as warts and papillomas, disappear with excellent cosmetic results. Good results have also been obtained in the treatment of keloid scars, cavernous nevi and corns.

The following are the chief advantages of the treatment:

1. It is possible to give a large dose and spare the surrounding tissues. This results in rapid healing and good cosmetic results.
2. The high dosage—up to 8,000 roentgens a minute—makes the time of treatment short, usually three or four minutes. Many patients can be treated during a day and their loss of time is minimal. It is also possible to administer large doses under anesthesia when surgical exposure of the lesion is necessary.
3. The method is economical and the running expenses are negligible. The majority of the cases can be treated in the outpatient department with a considerable saving to the hospital.

Danger of Food Contamination by Gas Attacks

The danger of food contamination by gas attacks was discussed at a conference of the food group of the Society of Chemical Industry. Dr. A. P. B. Page, of the Entomological Research Station of the Imperial College, Slough, said that methods were available for the detection and determination of all the known war gases. It seemed that many foodstuffs could be well protected against such gases. It should be possible to decontaminate most foodstuffs affected by vapors but few affected by liquids. Contamination was likely to be severe only on the surface of piles of food; thus big piles would be less affected than small ones.

Annual Meeting of the British Medical Association Canceled

The war has had a profound effect on medical arrangements. Many of the usual fixed events have been countermanded. The annual meeting of the British Medical Association, which was due to take place at Birmingham in the summer of 1940, has been canceled.

Blood Transfusion During the War

In 1937 Mme. Raba Deutsch de la Meurthe, on the initiative of Dr. A. Tzanck and with the cooperation of the Administration of Public Aid of Paris, founded the Centre de transfusions et de recherches hématologiques. A special building was constructed in the St. Anthony Hospital gardens in Paris and completely furnished. Its purpose is to furnish the necessary blood for all transfusions needed by physicians connected with the hospital services of the city, as well as by physicians in private practice, and to organize well equipped laboratories for the study of blood. The center began to function at once. Carefully chosen donors were recruited and permanent files set up where any physician at any time can quickly find donors and transfusion specialists. The donors were subjected to the usual tests. Blood groups were established and the universal donors kept. A large number of donors were selected and paid. In 1938 more than 8,000 blood transfusions were performed. Tzanck's apparatus was used, a syringe with two openings which permits aspiration of 10 cc. of blood and its immediate forcing into the veins of the patient. The blood is transmitted in complete protection from the air, with no need for citration. With the coming of the war, the center was assigned the task of organizing the blood service for wounded soldiers. The blood quantities required could be supplied only by conserved blood. An appeal, accordingly, was made through the press and radio to voluntary donors. The response was overwhelming. Those selected were given the requisite tests and from 200 to 250 Gm.

of venous blood was taken. A simple apparatus permits oxygenation and citration of the blood; it is poured into ampules that are promptly sealed and placed in refrigeration. Ten thousand goodwill donors of the universal type are expected. This will permit creating a constantly renewable stock of 500 liters of conserved blood, sufficient for all pressing needs, military as well as civilian. Blood shipments are made in specially wrapped packages and can be used two weeks after taking. Blood changes with age. The power of oxygen fixation and corpuscle resistance slowly diminishes, about the tenth to the twelfth day if physiologic solution of sodium chloride is added to the blood, from the thirteenth to the twenty-first day if sodium citrate is added, from the twentieth to the thirtieth day if a citrated dextrose solution is added. The blood groups do not change, nor do the serologic reactions, but the corpuscles do change from the fifteenth day on. The center has rejected the handling of the blood of dead bodies. Dr. Tzanck was commandeered for war service and has organized a sort of branch of the Paris center in the provincial city to which he was assigned. His place in Paris has been taken in the meantime by his associate Professor Sureau.

Absinth

Absinth has been known for its digestive and tonic properties. Galen often mentioned it. However, the word "absinth" today may mean several things. Absinth as a liqueur comes from Switzerland. It is an alcoholic beverage of different essences the majority of which belong to the genus *Artemisia*; that is, large and small absinthium, *Artemisia rupestris* and others. To these are often added Chinese anise (*Illicium verum*), hyssop (*Hyssopus officinalis*) and anise (*Carum pimpinella*). Its recipe has been modified in the course of its expansion in France and in the basin of the Mediterranean and it now contains chiefly anise, or rather anethol.

To a certain quantity of absinth, 1,000 cc. or more, the consumer adds water, which precipitates the essences and causes the solution to become muddy or thick (*louche*), appearing with fifteen measures of water and giving absinth the character of an *apéritif*. This quality of *louche* is demanded by the absinth drinker. An attempt was made to regulate the use of absinth in 1912, and a law was passed prescribing that it contain only 1 Gm. of essence per liter and titrate to not more than 40 per cent alcohol and that it contain no thujone or acetone bodies. Under these conditions it was impossible, with the customary quantities, to obtain the characteristic muddiness unless one also increased the quantities of the liqueur a great deal. The law, therefore, called for only a slight decrease in the quantity of essences absorbed but a great increase in that of alcohol. At the beginning of the World War in 1914 the consumption of absinth was strictly forbidden. But beginning with 1922 it was again authorized in continental France on the basis of the law of 1922, while in Algeria an absinth of 45 per cent alcohol with 2 Gm. of essence per liter was permitted. This absinth permitted the consumer to achieve the desired "muddiness." Fraudulent practices came into use. In southern France powder packages and small bottles of extract under the name of *pastis* were devised. The consumer dissolved them in any kind of alcohol. The powerful taste concealed the impurities, the butyl or amyl alcohols and even the strong flavor of high alcoholic content. Hence, to the harmfulness of toxic essences was added strong and impure alcohol.

A commission appointed by the minister of agriculture, with Professor Tanon, chairman, examined the toxicity of the essence of anise or rather of anethol, which has replaced it. They concluded that it was not harmful in small doses provided it was correctly distilled and contained no thujone. Anethol is a *para*-propylanisol, also called *iso*-estragol and in large doses induces convulsions. The commission admitted that if the use of absinth was to be permitted to continue it would be better to adopt

the regulations of Algeria; that is, to authorize 45 per cent alcohol, provided it was pure, and 2 Gm. of essences. In the Académie de médecine, Professor Vincent had a pledge put to a vote tending to complete suppression of absinth and similar beverages. However, the minister of finance will hardly renounce some six billions annually of revenue from alcohol, though it is collected at the expense of the national health.

Harmfulness of Mineral Dusts

At its last session, the Académie de médecine honored the memory of Harvey Cushing, who was one of its members and whose eulogy will be pronounced at the next meeting. It heard a fine funeral oration on Albert Brault, its recently deceased dean. Among the papers read at this session was that of A. Policard and J. Rollet on the harmfulness of mineral dusts tested by the corneal biomicroscope. There are, according to the authors, great differences among mineral dusts. To determine their harmfulness, subcutaneous injections of fine suspensions followed by local examinations of the tissues were made. Recently, intrapleural injections (Sayers) were practiced—an excellent but slow procedure, since one must wait weeks for the tissue response. The same is true of intrapleural or intratesticular injections. Intravenous injections, the results of which are quite precise, remain a laboratory approach. Artificial dust implantation of animals is not practical. Policard and Rollet conceived the idea of inserting into the thickness of a rabbit's cornea, after incision, an extremely small quantity of dry dust. The next day and the following days the cornea was examined with the aid of the corneal biomicroscope or the ocular microscope with the Süllstrand opening. This is a simple test and allows one to take precise cognizance of the reactions of the corneal parenchyma to the dust inserted. When finely pulverized charcoal is used, the least harmful of the dusts, the first reaction is a local edema. This is followed by a grayish infiltration of a cellular nature having minute punctations and being productive of a corneal disturbance around the mineral deposit. All these symptoms belong as much to the traumatism as to the irritation caused by the strange body and constitute the minimal reactions. In extreme cases, on the contrary, the reaction is violent. The edema appears early, is intense and extensive, may last for several weeks and leaves a cicatrice. Between these two extremes all intermediary degrees are found. The authors studied the toxicity of a whole series of dusts by this method and classified them according to their injuriousness.

Effect on Head Wounds of Transportation by Air

Professor Schaltenbrand, a neurologist, reported in *Der Deutsche Militärarzt* observations on transporting soldiers with head wounds by air. Rapid conveyance to special clinics should be done at once. Transportation by air may have serious consequences, but they do not exceed those incurred during long transportation by automobile. Schaltenbrand observed that the increase of atmospheric pressure had no positive effect on cerebral fluid pressure. Increased cerebral fluid pressure may result from incipient oxygen deficiency. Whenever it occurs, several factors are to be considered: (1) augmentation of cerebral fluid secretion in the plexus due to oxygen deficiency, (2) elevation of arterial pressure and (3) elevation of venous pressure. It is of prime importance to know that cerebral fluid pressure rises notably in healthy persons at greater altitude, but probably especially so if anemia through loss of blood or for other reasons is present. The application of these principles to the transportation by air of those with head wounds makes the following considerations mandatory: 1. Higher altitudes ought to be avoided as much as possible. 2. If higher altitudes

cannot be avoided, oxygen is to be supplied the patient in time without waiting until the 3,000 meter limit has been reached. 3. Circulation must be stimulated by strophanthin. The possibility that air may penetrate into the cerebral fluid spaces and cause a tendency of the brain to collapse is much greater than that of oxygen deficiency. Cerebral fluid pressure under conditions of aerial transportation not only varies with low pressure of the outer atmosphere but falls below normal level with atmospheric high pressure. The rise of cerebral fluid pressure in external atmospheric low pressure cannot be remedied with administration of oxygen. This consideration leads to further necessary precautions. 4. Patients with open brain injuries should be placed as horizontally as possible. 5. Wide skull clefts should not be closed before transportation. 6. A roentgen examination should be made before the flight. 7. If the ventricle is filled with air, the plane's ascent and descent should be carefully managed and greater fluctuations of altitude be avoided.

Meeting of the Roentgen Society

The main topics for discussion at this year's meeting of the Deutsche Röntgen Gesellschaft were the following: central x-ray institutes, x-ray tests for cardiac function, dosimetry, short wave therapy, effect of roentgen irradiation on the cells, sterilization by irradiation and x-ray serial tests. Holfelder's paper on the organization of x-ray service in universities and hospitals was occasioned by a similar paper read before this year's congress of German surgeons in which opposition was voiced against the central x-ray institute and the claim of surgeons advanced for x-ray divisions subject to their control. Holfelder pointed out that it was impossible for clinical specialists to be experts also in roentgenology. However, great stress should be laid on a thorough and many sided preparatory training of roentgenologists. Centralized institutes do not aim at monopoly. He admitted that clinicians need their own x-ray apparatus in their clinics for special occasions but also indicated that clinicians should limit themselves to the roentgenology of their special field. Roentgenologists should be trained only in central x-ray institutes. Representatives had been sent to this meeting by large clinical societies to discuss this fundamentally important problem. Schittenhelm, a Munich internist, set forth that the systematic training in the foundations of roentgenology must be given in independent special institutes but that the practical application of the principles acquired should be made in the x-ray divisions of the clinics and hospitals.

High voltage roentgen therapy, however, should be performed largely in independent x-ray institutes. Kirschner, a Heidelberg surgeon, explained that the diagnosis should be done in the individual clinics but that on the whole treatments should be administered in special institutes by roentgenologists. A forcible separation of x-ray diagnosis from the functions of the surgical clinics was out of the question. Besides, larger distances constituted a great disadvantage to the patient, especially in urgent cases. K. Hoede, a Würzburg dermatologist, pointed out that dermatologists had always stood aloof from centralization. In his opinion it was sufficient for a practicing physician who wishes to give his patients roentgen therapy to possess a general knowledge of the other fields of roentgenology. On the other hand, it was not sufficient for a roentgenologist to possess only a superficial knowledge of cutaneous and venereal diseases. The specialist, therefore, should be consulted before and during therapeutic management. He did not doubt that too many skin diseases were treated in x-ray institutes. Dermatologic clinics ought to be included in instruction on roentgen therapy. Holfelder indicated that the desire of roentgenologists for centralized institutes was not motivated by monopolistic intentions to encroach on the activities of the clinicians. The discussions at this meeting may have helped to clarify the situation, for previously roentgenologists had made larger

demands. These discussions bear also on the new medical curriculum requiring students to take a two hour course for one semester in roentgenology.

M. Bürger, a Leipzig clinician, and W. Teschendorf, a Cologne roentgenologist, presented a joint paper on x-ray examinations for cardiac functioning. Bürger set forth that it was better to speak of examinations for circulatory functioning. The examinations were based more or less on the observation of strains on the regulatory mechanism that takes care of an orderly interplay between circulation and respiration. What is observed is arbitrarily induced modification of the size, shape and movement of the heart and its large vessels. The size of the heart is essentially a function of its condition of fullness, a condition which can be influenced by suction (Müller's test) or pressure (Valsalva's test). X-ray examinations of changes in the size of the heart can acquire value for functional tests of the circulation only if all the circulatory conditions and the electrocardiographically perceptible disturbances of cardiac action, if present, are considered.

Reindell, of Freiburg, discussed the effect of sports on the heart, especially that of winners in competitive games. The question whether hearts enlarged by athletic exercises are to be considered as damaged does not receive a uniform answer. He himself denies it, supported by electrocardiographic and kymographic investigations. Neither does he accept the view that the youthful heart inclines more to enlargement than that of the older sportsman. It may be assumed that the heart of the sportsman eliminates its residual blood after strain and thus increases its efficiency.

Rajewski, of Frankfurt-on-the-Main, and Schliephake, of Giessen, discussed short wave therapy. Long wave diathermy, they said, had disappeared almost altogether. The generally used wave length of 3 meters did not yet conform to the best conditions for the "selectivity factor"; 1 meter was more favorable. Also the problem of dosage, he said, might soon be sufficiently clarified. In the biology of high frequency currents attention should be called to the fact that the presence of "specific effects" is not sufficiently proved. In fact, much was still doubtful in this field. The 1 meter wave seemed to possess a superior penetration but was accompanied, as Schliephake pointed out, by certain dangers. Therefore, only specially trained and experienced physicians should employ it.

A. Hintze, a Berlin roentgenologist at the surgical clinic of the university, reported on the results of the use of irradiation on carcinomas. During the years 1912-1925 about 5,000 cancer patients were treated, about 3,400 with roentgen rays or radium. A change has set in; more patients are being therapeutically managed with irradiation or irradiation in combination with surgery than by surgery alone. The majority of permanent cures were effected in patients subjected either exclusively to roentgen therapy or in combination with surgical intervention.

Gauss, of Würzburg, and Pickhan, of Berlin, discussed sterilization by means of irradiation. Originally the German laws on sterilization permitted surgery only. Since February 1936, roentgen rays and radium are allowed under certain conditions. A questionnaire addressed to centers possessing legal authority to sterilize elicited the information that 95 per cent of the patients were operated on and 5 per cent were treated with roentgen rays; of the latter, four fifths received roentgen and one fifth, radium therapy. The results of irradiation, with few exceptions, were entirely satisfactory. Secondary effects were relatively few and insignificant compared with those attending surgery. Impairment of the ability to work, he said, because of roentgen therapy was not demonstrable.

Value as Evidence of Blood Group Determination

At the request of the reich's minister of the interior, the Robert Koch Institute for Infectious Diseases in Berlin has rendered an official expert opinion on the value of blood group

determination as legal evidence (THE JOURNAL, July 2, 1933, p. 72). The report contains the following statements: The evidential value of the blood groups O, A, B and AB and of the M, N and MN characteristics of the blood corpuscles has recently been challenged in different ways. The arguments advanced against the validity of the blood groups are (1) that qualitative changes (mutations) of the genes can occur and (2) that the genes may be hindered in their development so that a structure genotypically present may not receive phenotypic evolution. These objections are answered in the expert opinion as follows: 1. In extensive scientifically performed investigations of heredity and family descent, not a single case of mutation of genes has been established. 2. Factors restrictive of gene development are of no significance for practical purposes. Therefore they offer no scientific basis for limiting the evidential value of the blood groups. The limitations and fallibilities of the methods, the report continues, are sufficiently known to all experts. In all cases in which these methods yield univocal results, the blood group of the individual whose sample has been taken is assured. If the results are equivocal, e. g. defective types or blood samples of the newborn in whom the presence of isobodies cannot be verified, the blood group is not reliably determinable. For that reason, experts must always clearly indicate whether univocal results have been obtained or not.

This judgment of the Robert Koch Institute was based on a questionnaire addressed to experts. All of them agree, on the basis of thousands of observations, that the hereditary transmission of blood group characteristics of A and B and those of the red corpuscles M and N can be safely relied on. If performed according to the regular method, the procedure for the blood groups O, A, B and AB and for the characteristics of the red blood corpuscles M and N can fulfil all legally required conditions. There is no other hereditary characteristic in human beings the hereditary evolution of which has been so fully reexamined and confirmed. The alleged mutability of the blood group of an individual and the deviations from the acknowledged laws of heredity formerly asserted were found to be due to errors of procedure or involved illegitimate offspring.

Only two exceptions exist to the validity of the observations just formulated and to the conclusions to be deduced from them: 1. The possibility of a feeble erythrocytic characteristic N(N₂). Only two cases have been observed in the literature in which the N trait showed too feeble an evolution to permit immediate verification. The Robert Koch Institute has therefore taken the position that the conclusions derived from accepted and correctly performed procedures possess a probability bordering on certainty if the negation of paternity is founded on the absence of N, whereas paternity cannot be denied in the presence of a feeble N(N₂). This probability is exceedingly great because blood samples with feeble N can nowadays be definitely recognized as possessive of a N content, because of the precautions provided. Consequently the two cases mentioned cannot constitute an argument against the reliability of the M and N determinations. 2. Subordinate groups of A (A₁/A₂) and AB (A₁B/A₂B). A high degree of probability attaches to the conclusions derived from observations based on correctly performed procedures of the subordinate blood groups just mentioned. However, statistical material on a large scale is not yet available to permit a categorical statement.

The opinion is summarized in the following words: If paternity can at all be excluded on the basis of blood group examination, all other combinations admit of conclusions that possess absolute certainty, provided the blood group determinations have been made in a scientifically unobjectionable manner.

ITALY

(From Our Regular Correspondent)

Sept. 22, 1939.

Leishmaniasis in Italy

Dr. Pullé, of Riccione, in a lecture before the Società Medico-Chirurgica della Romagna, discussed the clinical forms of leishmaniasis. The insect which transmits leishmaniasis is unknown. Probably various insects which fly during the day may transmit the disease. Rodents are highly receptive but they do not directly transmit the disease.

Professors Monti and Poggi reported on a large focus of cutaneous leishmaniasis which developed at Forlì and was observed by the speakers. In a municipality of the province, sixty cases were found. The twenty patients who had local injections of from 0.05 to 0.1 cc. of atabrine, according to Flarer's technic, recovered. The technic of administration is simple. The leishmaniotic nodules regress in ten or twenty days. The speakers showed photographs, microscopic preparations and photomicrographs. They presented four patients who had had the atabrine treatment.

Professor Bartolotti discussed cutaneous leishmaniasis. The speaker found, by microscopic and bacteriologic studies, that the changes in the epidermis due to *Leishmania* are similar to those in the epithelial cells due to *Microbacterium leprae*. The reticulo-endothelial cells are phagocytic for leishmania.

Professor Gentili reported three cases of visceral leishmaniasis in children. Two patients were natives of the province of Toscana and the other came from the region of Calabria. *Leishmania* was identified in one in the bone marrow which was taken by sternal puncture. In the other the parasite was identified in material taken from puncture of the spleen. The Auricchio-Chieffi reaction gave positive results in all three cases. The speakers found that the euglobulin fraction of the blood proteins was increased. They believe that the positive results of the Auricchio-Chieffi test are associated with the increase of the protein fraction.

Vascularization of Human Testicle

Professor Balice recently lectured to the Accademia delle Scienze Mediche e Chirurgiche, of Naples, on primary tuberculosis of the epididymis and testicle. The speaker recently carried on an x-ray study of the vascularization of the human testicle after having injected a thorium preparation into the spermatic artery. The roentgenograms show that the vascular supply of the testicle is provided by the spermatic artery and its branches, which bifurcate through the testicular parenchyma. The roentgenograms of the epididymis and the body of Highmore show a uniform dark shadow from the blood vessels. It cannot be determined whether the blood vessels originate only in the spermatic artery or in both the artery and blood vessels at the body of Highmore. Blood vessels of decreasing caliber from the body of Highmore to the free surface of the parenchyma can occasionally be seen in the roentgenograms. Probably they originate in central blood vessels. The speaker believes that tubercle bacilli come simultaneously to the epididymis and testicle through the blood. Early in the development of tuberculosis the disease is more acute in the epididymis than in the testicle because of the different blood supply of either structure. Tuberculous orchiepididymitis develops in most cases from the hematogenic route. However, in a few cases tuberculosis may be propagated by a process of continuity from the prostate and seminal vesicles to the epididymis and to the testicle. When this is the case, the primary seat of tuberculous granuloma is intracanalicular. The treatment is conservative, by roentgen irradiation. When the lesion is in the epididymis and the testicle is not involved by tuberculosis, an epididymectomy is indicated, after which the results of roentgen treatment are satisfactory.

Personal

Prof. Galeno Ceccarelli, professor of clinical surgery at the University of Perugia, was transferred to the same position at the University of Padua. Professor Ceccarelli graduated in 1913, after which he was appointed to the chair of surgical pathology at the University of Bari. He has published articles on pathologic histology of primary cancer of the epidermal structure of the gallbladder, pedunculated tumors of the liver and malignant tumors of the testicle. He was awarded a prize by the Concorso Nazionale Zanetti for his method of performing cutaneous transplantations in man. He studied the influence of the endocrine system in the regeneration of the skin and bones and also conducted clinical and experimental work on heterotopic ossification. He has written more than seventy articles on surgery, especially on torsion of the gallbladder and the painful symptoms of stagnation of the gallbladder.

Clinical Courses in Hospitals

New clinical courses in the hospitals of Rome were recently opened. The courses form a part of the university curriculum for physicians. The aim is to give new physicians special practice in clinical diagnosis and treatment of patients. Special attention is given to improvement in making diagnoses, determining proper indications and doses of drugs and other therapeutic procedures.

Marriages

WILLIAM SPEARS RANDALL JR., New Orleans, to Miss Hattie Louise Stapleton of El Paso, Texas, in San Antonio, recently.

RICHARD H. ARIMIZU, Hilo, Hawaii, to Miss Millicent Hume of Alliance, Ohio, in Honolulu, August 30.

COURTLAND PRENTICE GRAY JR., Monroe, La., to Miss Betty Eastland Ormond of Forest, Miss., September 9.

ANNA MAXWELL, North Reading, Mass., to Mr. Jerome A. Morris of Moncton, N. B., Canada, October 3.

JOSEPH BOISLINIERE GRINDON JR., St. Louis, to Miss Mary Ann Murray of Carlyle, Ill., September 27.

WARNER LEE WELLS, Raleigh, N. C., to Miss Rebecca Ann Atzrod of Clarksburg, W. Va., October 7.

MICHAEL J. STIEF, Mount Carmel, Pa., to Miss Margaret Mary Graham of Shenandoah, Pa., July 15.

WILLIAM ERNEST COLEMAN JR., Birmingham, Ala., to Miss Betty Brown of Eastaboga, September 30.

ISAAC EMERSON HARRIS JR. to Miss Mary Elizabeth Teer, both of Durham, N. C., in September.

EDWIN C. GALSTERER, Saginaw, Mich., to Miss Alma Foerster of Holyoke, Mass., September 25.

LEWIS E. ABRAM, Fitzgerald, Ga., to Miss Doris Friedman of Madison, in Athens, September 10.

EARL E. HOUCK JR., Du Bois, Pa., to Miss Katherine Marie Ulrich of Peoria, Ill., September 16.

JAMES MORRIS HIGGINBOTHAM to Miss Sue Dobbins, both of Chattanooga, Tenn., September 6.

LEMUEL PHOTO JAMES JR., James, Ga., to Miss Ila Ellene Walker in Atlanta, September 20.

BENZION C. BARON, Wakefield, Mich., to Miss Marion A. Carter of Crystal Falls, October 8.

HENRY H. MERRELL, Yorkville, Ill., to Mrs. Frank Lincoln Johnson of Chicago, September 9.

DAVID HALE CLEMENT, Boston, to Miss Constance Chambers of Litchfield, Conn., October 7.

JOHN D. FITZGERALD, Roxboro, N. C., to Miss Betty Offerman at Durham, September 5.

RAYMOND JAMES KAY, Wayne, Pa., to Miss Eva P. Welland of Gulph Mills, recently.

LEON E. POLLOCK, Spokane, Wash., to Miss Jean Berry of Portland, Ore., August 13.

REES MORGAN, Roanoke, Va., to Miss Dorothy Hazelwood at Richmond, September 30.

RALPH L. HIGH to Miss Jeanne Price, both of Chicago, September 1.

Deaths

William Battle Malone ☉ Memphis, Tenn.; *Memphis* (Tenn.) Hospital Medical College, 1899; formerly professor of surgery and clinical surgery at the University of Tennessee College of Medicine; past president of the Tennessee State Medical Association, Memphis and Shelby County Medical Society and the American Association of Railway Surgeons; member of the Southern Surgical Association; fellow of the American College of Surgeons; served during the World War; on the staffs of the Methodist Hospital and St. Joseph Hospital; aged 64; died, September 4, of acute hemorrhagic encephalitis.

Bernard Portis ☉ Chicago; Rush Medical College, Chicago, 1921, died suddenly of heart disease November 1, aged 42. Dr. Portis was assistant professor of surgery in the University of Illinois College of Medicine and associate attending surgeon in Michael Reese Hospital. Previous to the heart disease, which proved to be fatal, he had suffered an attack of toxic encephalopathy. Dr. Portis is survived by two brothers who are physicians—Drs. Milton and Sidney A. Portis.

Max Halle, New York; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1898; member of the Medical Society of the State of New York and of the American Academy of Ophthalmology and Otolaryngology; on the staffs of the Broad Street Hospital and the New York Polyclinic Medical School and Hospital; aged 66; was killed, September 5, near New Castle, Del., in an automobile accident.

Newton J. Coker, Canton, Ga.; University of Georgia Medical Department, Augusta, 1893; member of the Medical Association of Georgia; past president of the Cherokee County Medical Society; for many years chairman of the city and county board of education; served during the World War; founder of a hospital bearing his name; aged 71; died, September 11, of coronary occlusion.

Robert Logan Jones, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1898; member of the Tennessee State Medical Association; past president of the Nashville Academy of Medicine and of the Davidson County Medical Society; served during the World War; city bacteriologist; on the staff of the Protestant Hospital; aged 68; died, September 15.

Donald Wallace Porter ☉ New Haven, Conn.; Harvard Medical School, Boston, 1912; clinical professor of pediatrics at Yale University School of Medicine; member of the American Academy of Pediatrics and the New England Pediatric Society; served during the World War; on the staff of the New Haven Hospital; aged 53; died, September 8, of coronary occlusion.

Cornelius D. Mulder, Spring Lake, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1903; member of the Michigan State Medical Society; for many years member of the school board; on the staff of the Hackley Hospital, Muskegon, and the Elizabeth Hatton Memorial Hospital, Grand Haven; aged 65; died, September 6, of metastatic carcinoma.

Walter E. Ward, Owosso, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883; member of the Michigan State Medical Society; past president and secretary of the Shiawassee County Medical Society; health officer; aged 78; on the staff of the Memorial Hospital, where he died, September 10, of cerebral hemorrhage.

Harry Clay Smith, Missoula, Mont.; Bellevue Hospital Medical College, New York, 1894; member of the Medical Association of Montana; fellow of the American College of Surgeons; on the staffs of the Northern Pacific Beneficial Association Hospital and St. Patrick Hospital; aged 67; died, September 13, of heart disease.

Benjamin Hook Ritter, McCordsville, Pa.; Western Reserve University Medical Department, Cleveland, 1886; member of the Medical Society of the State of Pennsylvania; for many years on the staff of the Lewiston (Pa.) Hospital; past president of the Juniata County Medical Society; aged 80; died, August 27.

John Alexander Macgregor ☉ London, Ont., Canada; Western University Faculty of Medicine, London, 1892; an Associate Fellow of the American Medical Association; professor emeritus of medicine at his alma mater; fellow of the American College of Physicians; aged 67; died, September 20, of cerebral hemorrhage.

Rees Bynon Rees, Bakersfield, Calif.; University of Maryland School of Medicine, Baltimore, 1900; Harvard Medical School, Boston, 1901; member of the California Medical Association; owner of a hospital bearing his name; aged 71; died, August 19, of coronary embolus, adenoma of the prostate and diabetes mellitus.

James Francis Rice, Watertown, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1902; fellow of the American College of Physicians; past president of the Buffalo Academy of Medicine; on the staffs of the House of the Good Samaritan and the Mercy Hospital; aged 66; died, August 3.

George Wallace Jarman, Princess Anne, Md.; Bellevue Hospital Medical College, New York, 1888; fellow of the American College of Surgeons; director of the Peninsular General Hospital and member of the hospital executive staff; aged 77; died, September 19, of acute myocarditis.

Maurice Isaac Stein ☉ Harrisburg, Pa.; University of Maryland School of Medicine, Baltimore, 1909; past president of the Harrisburg Academy of Medicine; served during the World War; served on the staff of the Harrisburg Hospital in various capacities; aged 52; died, August 15.

Arthur Henry Harms, Knoxville, Ill.; Rush Medical College, Chicago, 1904; member of the Illinois State Medical Society; member of the board of education; aged 58; secretary of the staff of the Galesburg (Ill.) Cottage Hospital, where he died, September 21, of coronary thrombosis.

William Bryan Summerall, Atlanta, Ga.; Tulane University of Louisiana School of Medicine, New Orleans, 1896; veteran of the Spanish-American and World wars; formerly medical superintendent of the Grady Memorial Hospital; aged 74; died, September 5, of heart disease.

Leroy Alton Luce ☉ Boston; Tufts College Medical School, Boston, 1906; member of the American Psychiatric Association and the New England Society of Psychiatry; aged 59; died, September 27, in the West Suburban Hospital, Oak Park, Ill., of carcinoma of the lungs.

Lehnor Alfred McComb ☉ Tulsa, Okla.; Baylor University College of Medicine, Dallas, Texas, 1918; fellow of the American College of Surgeons; on the staff of the Morning-side Hospital and St. John's Hospital; aged 45; died, September 1, of a self-inflicted bullet wound.

John Davis Duckett, Houston, Texas; University of Nashville (Tenn.) Medical Department, 1898; Vanderbilt University School of Medicine, Nashville, 1899; member of the State Medical Association of Texas; aged 73; died, August 31, of congestive heart disease.

Max William Vieweg, Wheeling, W. Va.; University of Maryland School of Medicine, Baltimore, 1917; member of the West Virginia State Medical Association; served during the World War; on the staff of the Ohio Valley General Hospital; aged 55; died, August 13.

Charles Paxton Stackhouse ☉ Sandpoint, Idaho; Medical-Chirurgical College of Philadelphia, 1898; served during the World War; past president and secretary of the Bomer County Medical Society; on the staff of the Graham Hospital; aged 68; died, August 8.

Fred Wells Granger ☉ Surgeon Lieutenant Commander, U. S. Navy, Houston, Texas; Yale University School of Medicine, New Haven, Conn., 1918; entered the Navy in 1919; aged 48; died, August 22, in the Methodist Hospital of suppression of urine.

Richard Stephenson, West Lebanon, Ind.; Barnes Medical College, St. Louis, 1898; member of the Indiana State Medical Association; formerly county health commissioner; aged 72; died, September 1, at Rochester, Minn., of coronary sclerosis.

Burton Roy Miller, Tiffin, Ohio; Ohio Medical University, Columbus, 1897; member of the Ohio State Medical Association; veteran of the Spanish-American War; formerly county coroner; aged 74; died, September 16, of coronary occlusion.

Fred Harrison Schleich, Chicago; Chicago Medical School, 1926; member of the Illinois State Medical Society; on the staff of the Illinois Masonic Hospital; aged 50; died, September 16, of cerebral hemorrhage, arteriosclerosis and hypertension.

Leon Brinkmann, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1887; formerly on the staffs of the Jewish Hospital, Mount Sinai Hospital and St. Agnes Hospital; aged 72; died, August 23.

Beatrice Alma Reed Chatigny, Taunton, Mass.; Tufts College Medical School, Boston, 1913; formerly on the staff of the Taunton State Hospital and the Northampton (Mass.) State Hospital; aged 48; died, August 18.

John Sebring, Bellefonte, Pa.; Jefferson Medical College of Philadelphia, 1896; member of the Medical Society of the State of Pennsylvania; on the staff of the Centre County Hospital; aged 68; died, August 11.

Philip Richard Flanagan, Chatham, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; aged 73; veteran of the Spanish-American War; died, August 4.

John Frank Kilroy, Detroit; Detroit Homeopathic College, 1911; member of the Michigan State Medical Society; city physician; aged 59; died, September 9, in the Alexander Blain Hospital of pneumonia.

Siegfried F. Bauer * New York; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1902; aged 60; died, August 30, in Los Angeles, of septic infarction of the lung.

Theodore H. Thordarson, Minneota, Minn.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897; formerly health officer; aged 74; died, August 2.

Winston W. Barnard, Headland, Ala.; Memphis (Tenn.) Hospital Medical College, 1894; aged 79; died, August 22, in the Moody Hospital, Dothan, of a carbuncle on the neck and chronic myocarditis.

Robert Andrew Jacobsen * Exira, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1894; aged 60; died, September 6, in South Haven, Minn., of myocarditis.

Joseph Jarvis, Riverside, Calif.; Bellevue Hospital Medical College, New York, 1866; Victoria University Medical Department, Coburg, Ont., Canada, 1867; aged 96; died, August 25, of senility.

John Herbert Callen, Oakland, Calif.; Homeopathic Medical College of Missouri, St. Louis, 1890; aged 70; died, August 3, of strangulated inguinal hernia and tuberculosis of the lungs.

Edward von Adelung, Oakland, Calif.; University of California Medical Department, San Francisco, 1892; aged 72; died, August 25, of cerebellopontile angle tumor and cerebral arteriosclerosis.

Charles Frederick Mains, Boston; Harvard Medical School, Boston, 1896; member of the Massachusetts Medical Society; served during the World War; aged 67; died, August 17.

Charles Rudderow Hutcheson * Camden, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1920; aged 43; died, September 22, of a self-inflicted bullet wound.

William Diamond Sweet, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1931; aged 33; on the staff of the Western Hospital, where he died, August 14.

Frank Dunster White * Milford, Mass.; University of Vermont College of Medicine, Burlington, 1897; formerly on the staff of the Milford Hospital; aged 64; died, August 28.

Robert F. Peak, Louisville, Ky.; University of Louisville (Ky.) Medical Department, 1880; also a lawyer; aged 80; died, August 16, of hypertrophy of the prostate and heart disease.

Howard D. Manchester, Peoria, Ill.; Hahnemann Medical College and Hospital, Chicago, 1884; aged 79; died, September 4, in the Methodist Hospital of coronary arteriosclerosis.

William Fraser Bryans, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1890; for many years member of the board of education; aged 78; died, September 28.

Charles Thomas McLean, Hallsville, Ill.; University of Missouri School of Medicine, Columbia, 1879; aged 83; died, September 10, in the Mennonite Hospital, Bloomington.

Ellie H. Putman, Cuero, Texas; University of Tennessee Medical Department, Nashville, Tenn., 1892; health officer; aged 73; died, August 24, in the Lutheran Hospital.

Leslie Lamb, Lorimor, Iowa; Keokuk (Iowa) Medical College, 1896; member of the Iowa State Medical Society; aged 69; died, August 5, in Van Nuys, Calif.

John Joseph Mulvanity, Nashua, N. H.; Tufts College Medical School, Boston, 1913; member of the New Hampshire Medical Society; aged 57; died, August 13.

David Salinger, Chicago; University of Maryland School of Medicine, Baltimore, 1894; aged 80; died, September 17, of cerebral hemorrhage and arteriosclerosis.

Thomas Raymond Dorris, Nanticoke, Pa.; Jefferson Medical College of Philadelphia, 1925; on the staff of the Mercy Hospital; aged 40; died, August 5.

Samuel J. Litz * Chicago; Chicago College of Medicine and Surgery, 1916; for many years member of the board of education; aged 56; died, September 10.

Winfield Benjamin Trickey, Pittsfield, Maine; Medical School of Maine, Portland, 1913; member of the Maine Medical Association; aged 57; died, August 17.

Charles Chester Cottrell * Scotia, Calif.; Cooper Medical College, San Francisco, 1907; chief surgeon to the Scotia Hospital; aged 56; died, August 14.

Albert Lincoln Spanogle, Altoona, Pa.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1882; aged 78; died, August 10.

Randall Schuyler, Long Beach, Miss.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1877; aged 80; died in August.

Adam Emory Kauffman, Chicago; Rush Medical College, Chicago, 1885; aged 82; died, September 3, in the Presbyterian Hospital of coronary sclerosis.

Ernest Max Sasville, Collinsville, Ill.; Northwestern University Medical School, Chicago, 1902; aged 76; died, August 27, of chronic myocarditis.

Charles Reuben Buck, Columbus, Ohio; Pulte Medical College, Cincinnati, 1902; aged 62; died, September 1, of a self-inflicted bullet wound.

A. R. Lydy, Willard, Ohio; Hahnemann Medical College and Hospital, Chicago, 1883; aged 86; died, September 1, of cerebral hemorrhage.

Berton Mell Bishop, Archer, Fla.; College of Physicians and Surgeons, Baltimore, 1890; aged 70; died, August 22, of organic heart disease.

Lynn Noah Daniel Kunkel, Pittsburg, Calif.; University of California Medical School, San Francisco, 1932; aged 36; died, July 26.

George Thompson Pool, Vader, Wash.; Barnes Medical College, St. Louis, 1893; aged 74; died, August 26, in a hospital at Olympia.

Clarke Eugene Hinman, Syracuse, N. Y.; New York Homeopathic Medical College and Hospital, 1895; aged 80; died, August 27.

Arthur Wellington Ligon, Oxford, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1884; aged 80; died, August 18.

William J. Casteel, Blairsville, Ga.; Tennessee Medical College, Knoxville, 1898; aged 75; died, August 26, of an overdose of amylal.

James W. Clark, Columbus, Ga.; North Carolina Medical College, Davidson, 1906; aged 56; died, August 24, of cerebral hemorrhage.

Julius Schneyer, Philadelphia; Jefferson Medical College of Philadelphia, 1909; aged 64; died, August 8, of coronary thrombosis.

Buchanan Burr, Yarmouthport, Mass.; Harvard Medical School, Boston, 1879; aged 83; died, August 11, of coronary thrombosis.

Henley Abraham Stark, Cleveland; Cornell University Medical College, New York, 1937; aged 26; was drowned, August 12.

Abner William Shultz, Lebanon, Pa.; Jefferson Medical College of Philadelphia, 1870; formerly coroner; aged 93; died, August 19.

Jessie Boggs Stoner, Berlin, Pa.; Woman's Medical College, Chicago, 1889; aged 74; died, August 28, of diabetes mellitus.

Vincent D. Krout, Mechanicsburg, Ohio; Medical College of Ohio, Cincinnati, 1897; aged 70; died in August of angina pectoris.

Frank E. Shepardson, Painesville, Ohio; Indiana Eclectic Medical College, Indianapolis, 1889; aged 77; died, August 22.

Milton Armstrong Griffith, Lintlaw, Sask., Canada; Manitoba Medical College, Winnipeg, 1904; died, August 9.

Peyton H. Calloway, Beckley, W. Va.; Leonard Medical School, Raleigh, N. C., 1901; aged 69; died, August 1.

Henry LeHardy, Chattanooga, Tenn.; Savannah (Ga.) Medical College, 1875; aged 86; died, August 15.

Edward Linwood Emrich, Los Angeles; Rush Medical College, Chicago, 1892; aged 69; died, August 8.

Joseph Clyde Renwick, Warren, Ill.; Rush Medical College, Chicago, 1904; aged 58; died, August 29.

Bureau of Investigation

PEPPLES PEP-YOU-UP

The William Everrette Fraud

William Everrette carried on a piece of mail-order quackery from Philadelphia that has been declared a fraud and debarred from the mails. Everrette used such trade names as "Pepples Co.," "Pepples Pep-You-Up Co." and "W. E. M. E. Medicine Co." Everrette called himself "Doctor" and claimed to have studied "naturopathy" and to have been licensed by the state of New Jersey to practice "naturopathy." The Post Office fraud order, however, brought out that there had been accepted as evidence in this case a letter from the New Jersey Board of Medical Examiners stating that any one who intends to practice naturopathy in New Jersey must secure a license from that board to practice medicine and surgery and that William Everrette was not licensed to practice any branch of medicine and surgery in New Jersey.

The character of the Everrette fraud is shown in two of his advertisements:

SEXUAL VIGOR

For Men and Women

Try Pepples Pep-You-Up, non-injurious; no drugs or dope. The result is pep, power, energy and endurance. Bring back lost pleasures.

And another:

WEAK MEN AND WOMEN TOO

Do you suffer from lost PEP, weakness, piles, kidney, indigestion, nervousness, rheumatic pains, getting up nights. Say good-bye to these conditions. Buy a bottle of W. E. M. E. Herb Tonic. . . . \$1.00 per bottle. Cash with order.

These advertisements, according to the evidence in the case, were placed in "various newspapers."

On July 11, 1938, Hon. W. E. Kelly, Acting Solicitor for the Post Office Department, after a hearing in Washington at which Everrette and his attorney appeared, recommended in a memorandum to the Postmaster General that this fraud be debarred from the mails. The information in this article is based on the facts given in the Solicitor's memorandum and, in part, on material in the files of the Bureau of Investigation of the American Medical Association.

The "treatment"—whether for piles or for lack of "pep"—consisted of a liquid and some tablets. The liquid, according to government chemists, was a solution of epsom salt in water flavored with peppermint, together with some laxative drugs. Yet Everrette claimed in his advertisements that his stuff contained "no drugs." The tablets when analyzed were reported to consist essentially of plant tissue including a bitter and a laxative. Both the tablets and the liquid were reported to contain damiana, which the Council on Pharmacy and Chemistry has described in the "Epitome of the U. S. P. and N. F." (A. M. A. Press) as an "ingredient of nostrums for sexual debility in the male; mildly irritant, but otherwise probably inert."

The government charged that the claims made by Everrette that his "patent medicines" would enable sufferers from "kidney trouble," indigestion, piles, sexual weakness, and so on to "say goodbye to these conditions" were false and fraudulent. Even the physician whom Everrette got to testify in his behalf practically admitted the same thing.

The Post Office Department is not the only government agency that looked into this fraud. As long ago as March 1937 the Federal Trade Commission issued a complaint against Everrette, trading as W. E. & M. E. Medicine Co. The charge was not that the business was a fraud but that the claims made by Everrette were "exaggerated and misleading" and that such claims would cause "diversion of trade from competitors." The Commission's complaint allowed Everrette twenty days in which to file answers to the charge. Four months later (July 1937) the Commission reported that a hearing on the charge would be held in Philadelphia on July 30, 1937. Time passed! Ten months later (May 1938) the Commission declared that a hearing on the same case would be held in Washington, D. C., on May 27, 1938. More time passed! Four months later still (September 1938) the Commission again reported that a hearing on the same charges would be held in Washington on Sept. 28, 1938—more than two months after the Post Office Department had put this piece of mail-order quackery out of business! The

case was not finally settled until September 1939, when the Commission definitely ordered Everrette to cease representing that his "Herb Tonic" purifies the blood, relieves all acute pains, stimulates the sexual organs or system, or does some of the other things claimed for it.

The Post Office Department acted with less circumspection in Everrette's case. It notified him of the charges on April 28, 1938, and on July 14, 1938, his fraud was debarred from the mails.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Go-Gon 7-11.—Helm Co., Benton Harbor, Mich. Composition: Liquid, essentially small amounts of boric acid, zinc sulfate, a calcium compound, phosphates, glycerin and water; tablets, chiefly small proportions of ferrous sulfate and volatile oils (including santal, wintergreen and cubeb) with copaiba, and chalk coating. Fraudulently represented as effective in preventing and curing gonorrhea, discharges from urethra and bladder, and urinary complaints in general.—[N. J. 29444; February 1939.]

Minnequa Water.—Minnequa Springs, Canton, Pa. Composition: A lightly mineralized water of the bicarbonate type. Fraudulently represented as an effective treatment for impaired tissues, acid dyspepsia, constipation, gallstones, gravel, gout, diabetes, skin eruptions, rheumatism, neuritis, obesity, etc.—[N. J. 29262; December 1938.]

Ranol's (Dr.) Indian Black Tablets.—Suter Chemical Co., Altoona, Pa. Composition: Essentially methenamine, saltpeter, oil of juniper and plant drugs including buchu, bearberry, podophyllum and an emodin-bearing drug. Fraudulently represented to be effective for kidney and bladder disorders, etc.—[N. J. 29431; February 1939.]

Ranol's (Dr.) Indian Herb Tablets.—Suter Chemical Co., Altoona, Pa. Composition: Essentially aloe, podophyllum, gentian and red pepper. Fraudulently represented as an effective remedy for stomach, blood and liver disorders, sick headache, etc.—[N. J. 29431; February 1939.]

Sanettes (Mentholated Kerchiefs).—San-Nap-Pak Mfg. Co., Wheelwright, Mass. Composition: Tissue paper impregnated with menthol. Claims that it was "Useful during . . . hay fever and sinus irritations" and "Aids in clearing congested air passage" were declared fraudulent.—[N. J. 29258; December 1938.]

Saxon Blackberry Cordial Compound.—Saxon Co., Duquesne, Pa., and Cleveland, Ohio, and Royal Mfg. Co., Duquesne. Composition: Essentially water, sugar, glycerin and alcohol, with small amounts of salicylic acid and plant extracts, including ginger. Fraudulently represented as a remedy "For Diarrhea, Summer Complaint, Cholera Morbus, Cramps, Colic and similar complaints."—[N. J. 29270; December 1938.]

Shapley's Liniment.—Shapley Drug Co., Inc., Decatur, Ill. Composition: Essentially common salt with small proportions of ammonia and ammonium salts, and extracts of plant drugs, with camphor and water. Fraudulently represented as effective in rheumatism, neuralgia, neuritis, croup, etc.—[N. J. 29433; February 1939.]

Shapley's Stimulating Pills.—Shapley Drug Co., Inc., Decatur, Ill. Composition: Essentially plant drug extracts including a bitter, coated with baking soda and dextrose, and colored green. Fraudulently represented to stimulate the kidneys and bladder and to help backache, rheumatic pains, uric acid, gout, scanty urine, etc.—[N. J. 29433; February 1939.]

Shapley's Unguentum Camphoratum.—Shapley Drug Co., Inc., Decatur, Ill. Composition: Essentially a small amount of volatile oils including camphor, menthol and possibly eucalyptol, in a base chiefly of petrolatum and a small amount of paraffin. Fraudulently represented as a treatment for catarrh, hay fever, carache, influenza, neuralgia, tonsillitis, etc.—[N. J. 29433; February 1939.]

Trox Tablets.—Oxol Laboratories, Denver. Composition: Essentially charcoal, starch, magnesium carbonate, extracts of plant materials including saponins, and a small amount of oxyquinoline sulfate. Effectiveness as a treatment for urinary infections, cystitis, prostatic and venereal disorders was fraudulently represented.—[N. J. 29259; December 1938.]

Ward's Anti-Pain Remedy.—Dr. Ward's Medical Co., Winona, Minn. Composition: Essentially a small amount of volatile oils (including wintergreen, sassafras and mustard), with alcohol and water. Fraudulently represented as an effective treatment of lame back, rheumatism, neuralgia and lumbago.—[N. J. 29450; February 1939.]

Ward's Cough Syrup.—Dr. Ward's Medical Co., Winona, Minn. Composition: Essentially alcohol, ammonium chloride, chloroform and tarry material, with a small amount of plant extracts and aromatics. Fraudulently represented as effective in treating "certain disorders and diseases of the bronchial tubes and lungs, coughs, spasmodic croup, bronchitis, coughs, sore throat, pleuritic coughs, whooping cough, la grippe, croup, hoarseness, and kindred ills affecting the lungs and bronchial tubes, bronchitis, pleurisy, throat disorders and croup."—[N. J. 29450; February 1939.]

Correspondence

STANDARDIZATION OF BLOOD PRESSURE READINGS

To the Editor:—The report of the Committees for the standardization of Blood Pressure Readings appointed by the American Heart Association and by the Cardiac Society of Great Britain and Ireland recently appeared in *THE JOURNAL* (July 22, p. 294). The recommendations embodied in the report are excellent except for those of the American committee relative to diastolic pressure readings. The committees agree that "with continued deflation of the cuff, the point at which the sounds suddenly become dull and muffled should be known as the diastolic pressure." However, the American committee recommends that "if there is a difference between that point and the level at which the sounds completely disappear . . . the latter reading should be regarded also as the diastolic pressure." The British committee, on the other hand, "believes that except in aortic regurgitation it is nearly always possible to decide the point at which the change comes and this is the only reading that should be recorded."

From the physiologic point of view there is much to substantiate the British and little to support the American opinion in this matter. Ordinarily, of course, the difference between the diastolic readings obtained by using the sudden muffling of the sounds and the disappearance of the sounds is not more than from 5 to 10 mm. of mercury. However, in an occasional individual the sounds persist even to the 0 level and thus in the report the American committee recommends the recording of a blood pressure of 140/70-0. A diastolic pressure of 0 is possible only theoretically with a completely rigid vascular tree.

Recent studies have shown that there is reasonably close agreement between diastolic readings obtained in man by direct methods and by the indirect method of employing the appearance of the muffled sounds (*Ztschr. f. d. ges. Exper. Med.* 79:569, 1931; *THE JOURNAL*, Sept. 12, 1936, p. 853).

The diastolic pressure is considered to be the minimum pressure in an artery at the end of ventricular diastole. Only confusion can result from assigning two values to a single pressure level. In our courses in physiology for medical students we have for years discouraged the use of the disappearance of all sounds as a criterion for the diastolic pressure level and will continue to do so.

GEORGE E. WAKERLIN, M.D., Ph.D., Chicago.

Professor of Physiology and Head of the
Department of Physiology, University of
Illinois College of Medicine.

BIOGRAPHY OF DR. HARVEY CUSHING

To the Editor:—Mrs. Cushing has requested me to prepare a biography of her husband, and I should be most grateful to any one who wishes to make letters, anecdotes or other memorabilia available.

Copies of all letters, no matter how brief, are desired, and if dates are omitted it is hoped that, when possible, these may be supplied (e. g., from the postmark). If original letters or other documents are submitted, they will be copied and returned promptly.

A new medical library building is being erected at Yale University School of Medicine to receive Dr. Cushing's library and collections, including his letters, diaries and manuscripts. Any of his friends who wish, now or later, to present correspondence, photographs or other memorabilia for permanent preservation among the Cushing papers will receive the appreciative thanks of the university.

JOHN F. FULTON, M.D.,

333 Cedar Street, New Haven, Conn.
Yale University School of Medicine.

SILK IN SURGERY

To the Editor:—Your editorial in the October 7 issue of *THE JOURNAL* "The Renaissance of Silk in Surgery" is apropos, as silk for suturing has been relegated into disuse for too long a time. Some fifteen or eighteen years ago, in line with the current fashion, I began to employ clips in the closure of mastoid wounds. The results were not always satisfactory because of secondary infections. I decided that too much tension by the clips on the edges of the wound was responsible for necrosis of the tissue with the resulting difficulties; although these were not productive of actual bad results as to eventual union, the healing was delayed. Then I turned to catgut—plain or chromicized—with practically the same difficulties. For the past six years I have used silk in place of clips or catgut and, making sure that not too great tension on the sutures is exerted, I have not been bothered with any secondary necrosis and secondary infection. Your editorial remarks are directed particularly toward silk as opposed to catgut, but I would extend that opposition to include metal clips.

PHILIP FRANK, M.D., Schenectady, N. Y.

ILLEGITIMACY IN THE UNITED STATES

To the Editor:—May I express to you my deep appreciation of the editorial on illegitimacy in the United States, which appeared in *THE JOURNAL* September 30, page 1329.

We in New Jersey are engaged in the administration of a law which became operative Jan. 1, 1939, for a better control of the adoption situation, especially in relation to good social practice.

Previous to Jan. 1, 1939, adoption practice was most informal, easily commercialized and with no guaranty whatever that the child, the child's mother and the adopting parents were protected in any way.

No longer may individuals place children for adoption without subsequent review, on order of the court, of all the factors involved; this department and incorporated social agencies, qualified to serve children, are the instrumentalities to be used by the court in the necessary investigations which shall insure to the three parties concerned that their best interests are protected.

In addition, provision is made to protect the confidential nature of such transactions. We believe that we shall have informative material available in regard to this whole matter which may be useful in the future handling of the problem.

ELLEN C. POTTER, M.D., Trenton, N. J.

Director of Medicine, Department
of Institutions and Agencies.

DIFFICULTIES IN EVALUATING AN INSULIN PREPARATION

To the Editor:—The efficiency of a new insulin preparation is determined by its effect on the sugar metabolism of a diabetic patient who is receiving suitable quantities of food. Judgment is rendered difficult by unexplained variations in sugar excretion, though every effort has been made to control insulin dosage, diet, physical and mental activities and the like. It is probable that this annoying irregularity is occasioned by unknown limiting factors that are necessary for insulin activity. The profession is distressingly ignorant of this phase of carbohydrate metabolism, and it is to be hoped that further work by biochemists and physiologists will elucidate this question.

Another disturbing factor, more amenable to correction, is the lack of agreement among writers as to what constitutes acceptable regulation of the diabetic patient. A committee of men especially interested in diabetes might undertake to dispose of this problem.

LOUIS BAUMAN, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CANCER OF LUNGS

To the Editor:—The condition of my father, who is 62 years old, was diagnosed bronchial carcinoma of the squamous cell type (primary) in December 1938. Diagnosis was made by biopsy. Prior to that time he had a nonproductive cough for five months, some loss of weight and slight general debility. In January 1939 roentgen treatment was started over the upper right part of the chest, the site of the lesion. Each day he received 200 roentgens over the anterior and posterior portions of the chest. A total of 8,000 roentgens was given. Coughing was much less and generally he felt better as well as gaining several pounds. Seven months after conclusion of the first roentgen treatment, coughing became more pronounced and general debility more marked. An x-ray examination of the chest revealed an atelectatic area in the lower part of the right lung, involving most of the middle lobe and a small amount of the lower lobe. This of course was thought to be due to extension rather than possible damage by former roentgen treatment. Treatment was started over the new area, 200 roentgens anteriorly and posteriorly daily, a dose of 8,000 roentgens being contemplated. All treatment has been given at 200 kilovolts. There has been no reduction of the cough since treatment has been started and some nausea has been experienced. Will you please advise me what other treatment might help. Do you consider the roentgen treatment adequate? If not, please advise me as to the dosage and amount. I would also appreciate your comment on the expectancy of life.

M.D., Texas.

ANSWER.—The events described in this case are fairly typical of the results usually obtained in the roentgen treatment of cancer of the lungs. The treatment resulted in some degree of palliation, followed by recurrence. The second course therapy was less efficacious. This holds true for a second irradiation not only of cancer of the lungs but of other lesions as well. In all probability further roentgen or radium treatment would not be of value.

The prognosis of cancer of the lungs is somewhat as follows: One third of the patients die within three months, one third within six months and the other third within twelve to eighteen months.

INGESTION OF POTASSIUM PERMANGANATE

To the Editor:—Please give me what information you can on the ingestion of potassium permanganate. My inquiry is instigated by the discovery that a considerable number of men have been using potassium permanganate over a period of time going back several years in the self treatment of acute coryza and boils. For both conditions they claim that the material taken as a one-tenth molecular solution, one teaspoonful three times a day in a glass of water, is unusually efficacious. I shall appreciate any information you can give me on this subject.

H. H. Gay, M.D., Midland, Mich.

ANSWER.—Whatever action potassium permanganate has is due largely to its ability as an oxidizing agent, provided it is present in adequate quantities. Solutions of potassium permanganate have been used for destruction of morphine or strychnine, provided the poison is still in the stomach; but it should not be employed to the exclusion of gastric lavage. One thousand cc. (1 quart) of a 1:2,000 solution is used to wash the stomach, and it must be evacuated after a few minutes. It usually is of little value when the stomach contains much organic matter, but morphine and physostigmine are decomposed readily even in the presence of organic matter. In snake bite permanganate may be used to wash the incised wound and also to inject immediately around it, but little or none of the permanganate diffuses through the tissue, and it has no effect on any poison that has been absorbed. Potassium permanganate is a deodorant, germicide, irritant and astringent. It is used on mucous membranes, especially of the urethra, in dilutions of from 1:5,000 to 1:1,000. It has been used to disinfect the hands in surgery. The hand is dipped into the disinfectant solution until it is mahogany brown and then dipped into a warm saturated solution of oxalic acid and rinsed in sterile water. Solution of 1:500 is applied externally for excessive sweating of the feet (Useful Drugs). There are no indications other than those already given for the oral administration of the product. It is difficult to believe that it would be of any use for treatment in coryza or cutaneous abscesses. Potassium permanganate naturally reacts to the contents of the stomach, forming manganese compounds such as manganese oxide and possibly manganese chloride. Of late years it has been pointed out particularly that manganese as a metal is a dangerous substance, especially when it enters the

body in the form of dust by inhalation. When a workroom or mine contains as much as 2 mg. of manganese dioxide per cubic foot of air, severe poisoning may arise after long exposure. Lately there has come into prominence in some European countries a form of pneumonia attributed to manganese. This arises solely in towns or cities harboring manganese industries. However, persons not employed in the manganese industries apparently readily acquire the disease, owing to manganese dusts discharged into the general atmosphere. Low quantities of manganese have produced this form of pneumonia in experimental animals. While there is no proof that the oral intake of manganese will induce this condition, it seems likely that this substance will in the future be regarded as more dangerous than heretofore. Manganese pneumonia is well described in the "Proceedings and Papers of the Eighth International Congress for Industrial Medicine and Occupational Diseases" held in Frankfurt on the Main Sept. 26-30, 1938 (Leipzig, Georg Thieme, 1939) through three contributions, as follows:

1. Beobachtungen über Manganpneumonien, by Dr. D. Elstidt, O-ls, 2: 1014.
2. Die Manganpneumonie, by Prof. Dr. H. E. Böttner, Gortitz, 2: 1022.
3. Experimentelles zur Thomasschlackenstaub und Manganpneumonie, by Prof. Dr. K. W. Jotten und Dozent Dr. H. Reploh, Münster, 2: 1028.

SANOCRYSYN AND DREYER'S ANTIGEN IN TUBERCULOSIS

To the Editor:—Please give the merits and demerits of treatment of tuberculosis by sanocrysin and Dreyer's defatted antigen. M.D., Arizona.

ANSWER.—Since Möllgaard published the results of his study of sanocrysin and claimed its specifically curative effect in tuberculosis, the drug has been tried on patients by many investigators. There is no uniform opinion as to its place as a therapeutic agent. The predominant opinion in this country is that the drug is of little use.

Investigation has shown that the action of sanocrysin is due to stimulation of the natural defenses of the body and is not bactericidal, as proposed by Möllgaard. The cases most favorably affected are the acute or subacute types. Because it is difficult to determine the type that will react unfavorably, the treatment must be started with small doses and be increased according to the patient's tolerance. It has been found that patients with fibroid lesions are not benefited by the drug. Bronchopneumonic lesions pursuing an acutely progressive course are harmed by sanocrysin.

Various disturbing reactions have been observed in a large proportion of cases during the treatment which indicate that sanocrysin is not a safe remedy. The complications encountered are chiefly those of heavy metal poisoning. Vomiting and hiccups difficult to control may occur soon after the injection. Persistent high fever, gastric derangement, diarrhea and cutaneous eruptions have been frequently observed. Albuminuria, hematuria and symptoms of shock and collapse have been noted. There is strong evidence that sanocrysin affected unfavorably the trend of the disease and that it exerted harmful systemic effects because of its toxicity.

Dreyer in 1923 announced a diaplyte vaccine produced by treating killed tubercle bacilli with solution of formaldehyde and acetone. His work was based on slight experimental evidence. It has been shown to be capable of stirring up tissue reactions which resulted in active tubercle formation with caseation. Any supposed benefits were limited to a short period of time.

EPISCLERITIS PERIODICA FUGAX

To the Editor:—For many years a patient has had episcleritis periodica fugax. She has had numerous treatments, including opening of the sinuses, removal of the teeth, appendectomy, hysterectomy, tuberculin injections, allergy elimination diets, autogenous vaccines from the nose, sulfonamide, gynergen and protein shock therapy and many examinations including x-ray examinations of the chest and gastrointestinal tract, determination of the basal metabolic rate, sugar tolerance tests and the like. No cause has ever been discovered, nor has there been any favorable effect on the disease. Now the patient is desperate. Have you any suggestion? M.D., Louisiana.

ANSWER.—The best description of episcleritis periodica fugax is to be found in the second volume of Duke-Elder's Textbook of Ophthalmology of 1938. There is considerable space devoted to the discussion of the etiology of the condition and the author concludes with the following sentence: "The only treatment of value is systemic treatment, for local treatment is usually quite without effect." The one phase of etiology not sufficiently emphasized is that of a tuberculous allergy, which is apparently the cause in many cases. Long continued courses of tuberculin for desensitization have proved to be curative in some cases.

PNEUMOPERITONEUM FOR TUBERCULOUS ADHESIONS

To the Editor:—Will you kindly tell me the status of air inflation treatment done repeatedly in the hope of releasing abdominal adhesions from an old tuberculous peritonitis? How and when should it be done? Is there any proof of relief of obstructive symptoms?

Elizabeth Ford Love, M.D., Moorestown, N. J.

ANSWER.—The introduction of air into the peritoneal cavity, known as pneumoperitoneum, has been used for approximately a third of a century. It was originally employed primarily in the treatment of tuberculous peritonitis, since there was a belief that this condition was frequently brought under control by allowing air to enter the peritoneal cavity during laparotomy. It has also been used rather extensively in the treatment of intestinal tuberculosis.

Pneumoperitoneum is frequently instituted in an attempt to elevate and partially immobilize the diaphragm, the thought being to bring about partial rest of the diseased lung, as is believed to occur during pregnancy. It is also used in various diagnostic procedures. Probably pneumoperitoneum is valuable in the prevention of adhesions while tuberculous peritonitis is being brought under control, but it is extremely doubtful whether it is of any value in releasing abdominal adhesions from an old tuberculous peritonitis. The only possibility would be that it might change the position of abdominal organs, particularly parts of the intestine, to relieve the obstructive symptoms partially. If such symptoms are severe, however, one should not rely on pneumoperitoneum but should resort to surgical methods. There is one danger that should be kept in mind constantly when one attempts to introduce air into the peritoneal cavity, and it is particularly great if adhesions are present; it is the introduction of the air into a blood vessel. Patients have died almost instantly from air embolism while pneumoperitoneum was being attempted. To determine just when the needle is in free peritoneal space is more difficult than in the case of the pleural space, on account of the high negative pressure in the latter. When pneumoperitoneum is to be instituted, an ordinary artificial pneumothorax needle or instrument may be introduced approximately an inch to the right or left and one-half inch below the umbilicus. This area usually avoids the penetration of large blood vessels in the abdominal wall. When one is certain that the needle is in the peritoneal space, air may be introduced by the ordinary artificial pneumothorax equipment. Usually from 300 to 500 cc. suffices for each treatment. Percussion over the liver while the treatment is being instituted will usually result in a change from a flat to a somewhat resonant note if the air is reaching the peritoneal cavity.

GASTRIC CARCINOMA

To the Editor:—Of all gastric carcinomas, how many occur above the pyloric area? What is the usual type that occurs in the upper section of the stomach? Is there an accepted "classic symptomatology" of upper gastric carcinoma? What percentage of surgical cures has been reported?

M.D., Indiana.

ANSWER.—The incidence of gastric carcinoma above the antrum has been found to be about 50 per cent in many large series of surgically resected and postmortem specimens. When the lesser curvature is included, the figure rises to about 75 per cent. Some authors, among them Konjetzny, believe that many carcinomas of the lesser curvature are often carcinomas of the antrum with secondary extension along the lesser curvature. Konjetzny (*Der Magenkrebs*, Stuttgart, Ferdinand Enke, 1938, p. 158) in a series of resected specimens found only 18 per cent of the carcinomas to have arisen above the antrum.

Gastric carcinoma rarely causes characteristic early symptoms. Those above the antrum are no exception. Symptoms are often insignificant even when the lesion has progressed beyond the resectable stage. This is especially true of carcinoma of the fundus. On the other hand, carcinoma of the cardia may give relatively early symptoms of esophageal obstruction, but because of its surgical inaccessibility the earlier diagnosis leaves the poor prognosis unaltered. Later symptoms are usually not characteristic of the region of the stomach involved.

A variety of pathologic types of gastric carcinoma occur above the antrum and will be discussed together with surgical cures.

Surgical cures reported amount to from 1 to 5 per cent of all gastric carcinoma seen in large clinics. This figure, however, is misleading in an individual case, because in cases in which the lesion can be resected Balfour (*Surg., Gynec. & Obst.* 54:312 [Feb., No. 2A] 1932) reports 20 per cent to be ten year cures. Carcinomas above the antrum include those with the best and also those with the poorest prospect of surgical cure. As a group, carcinomas of the body and greater

curvature (from 10 to 15 per cent of all gastric carcinomas) offer the best hope for surgical cure. The borders are usually sharply demarcated, metastases are relatively late, and they are surgically accessible. Malignant linitis plastica or carcinoma fibrosum, found in less than 2 per cent of Minnes and Geschickter's series of 541 cases (*Am. J. Cancer* 27:740 [Aug.] 1936), is seldom cured. At operation it is difficult to differentiate involved from uninvolved areas, and even when a wide resection is done considerable carcinomatous tissue remains behind. Carcinoma of the cardia and fundus have poor prospects for surgical cure. Those of the lesser curvature are intermediate in the possibility of a cure, depending on the proximity to the cardia on one hand and the involvement of neighboring structures on the other. Carcinoma in this location metastasizes and invades adjacent organs relatively early.

PROBABLE ACUTE ULCUS VULVAE

To the Editor:—Thirteen months ago small blisters began to develop on the vulva of a girl aged 9 years. These lesions appeared at intervals of from seven to fourteen days and required from three to ten days to heal. I first saw the child four months ago. At that time the mucous membrane of the vulva appeared thin, and there were two or three tiny cracks near the clitoris. On the right labium majus there was a blister 1.5 by 1 cm. This was filled with a serosanguineous fluid. The mucous membrane over the blister broke after a few hours, leaving a shallow denuded area. This gave the child no discomfort, except on voiding, when the urine caused considerable burning and pain. The Wassermann reaction was negative; examination of the stool was negative for parasites. The child's weight was 77 pounds (35 kg.), which is 10 pounds (4.5 kg.) above the average for her age and height. The vaginal smear is negative for gonorrhea, for *Trichomonas vaginalis* and for monilia. Examination of the urine was negative for sugar on the first three examinations. On several occasions since, however, a trace of sugar has been found. This can be controlled by moderate limitation of carbohydrates. Treatment has been unsuccessful. She was given estrogenic substance as a suppository and has had local treatments with gentian violet, silver nitrate and silver picrate to no avail. I would appreciate any suggestions as to diagnosis and treatment.

M.D., Alabama.

ANSWER.—The blisters in this case may represent retention cysts of the sweat or sebaceous glands about the vulva, or they may be herpes genitalis. The latter has a tendency to recur and is usually located on the labia minora. Trauma such as from masturbation must be ruled out, particularly because of the presence of the tiny cracks near the clitoris. The most likely diagnosis, however, is *ulcus vulvae acutum*, first described by Lipschütz in 1913. The blisters in the present case may represent a prodromal stage of this disease. Wien and Perlstein (*THE JOURNAL*, Feb. 6, 1932, p. 461), who reported one of the first American cases, point out that the disease is characterized by the presence of ulcers which appear suddenly in the mucous membrane of the vulva or adjacent region in which *Bacillus crassus* is constantly found. This organism is apparently identical with Döderlein's vaginal bacillus. The lesions involute spontaneously after varying lengths of time with slight or no scar formation, depending on the depth of ulceration.

In the case reported by Wien and Perlstein, the lesions occurred in definite cycles directly related to the physical condition of the patient. Fatigue, nervous exhaustion and mild infections of the upper respiratory tract predisposed to the occurrence of the lesions.

The treatment is usually simple. The lesions heal quickly when treated with mild antiseptic washes or compresses. The persistent application of aluminum acetate packs to the vulva daily for a month will usually give permanent relief. Attention should also be paid to the patient's general physical condition, her diet, her periods of rest and her environment.

ARGYLL ROBERTSON PUPIL

To the Editor:—Is it possible to dilate a true syphilitic Argyll Robertson pupil adequately with a cycloplegic? Will the pupil return to normal after the patient has been cured by antisyphilitic treatment. If so, why?

Robert Emmet Jameson, M.D., Davenport, Iowa.

ANSWER.—In the article by Merritt and Moore (*The Argyll Robertson Pupil: An Anatomic-Physiologic Explanation of the Phenomenon, with a Survey of Its Occurrence in Neurosyphilis*, *Arch. Neurol. & Psychiat.* 30:357 [Aug.] 1933) is quoted the original description by Argyll Robertson of the pupillary phenomenon which bears his name. In the quotation appears this statement: "Strong solutions of atropine only induced a medium dilatation of the pupil." The imperfect dilatation of the Argyll Robertson pupil in response to installations with cycloplegics is characteristic of paralysis in the sympathetic innervation of the eye.

There are scattered reports of the return to normal of true Argyll Robertson pupils after artificial fever therapy in syphilis

of the central nervous system but, so far as is known, not after other forms of antisyphilitic treatment. Why the Argyll Robertson pupil should return to normal under such circumstances or indeed under any other circumstances is not known, since the exact mechanism of its production is also unknown.

SUSPECTED CERVICAL CARCINOMA AND BIOPSY

To the Editor:—What are the dangers in taking a biopsy with a cautery or knife in a case of tumor of the cervix which is probably malignant? My situation up here is such that with present facilities I am not able to do a microscopic section and all specimens are sent to the States. In a case of cancer would this tend to spread it, and if so is the danger great enough to warrant sending the patient out or doing a total hysterectomy rather than taking a biopsy and waiting a month? What would be the best way to make a biopsy to prevent spread? Would a loop on a diathermy be better than a cautery and how much better is that than a knife? Is it true that after cautery the lymph flow is to the wound and that after the knife it is away from the wound? What is the danger of dilating the cervical canal in the presence of a possible malignant growth in order to see it better?

David Hoehn, M.D., Fairbanks, Alaska.

ANSWER.—There is no definite evidence that there is danger in performing a biopsy on a carcinoma of the cervix with a sharp scalpel or cautery, provided the procedure is executed carefully. The danger of spreading the disease after biopsy in relation to the time interval between biopsy and therapy is a controversial question. On the whole, experience indicates that it is best to execute the therapeutic procedure as soon after the biopsy as possible. In mentioning the question of hysterectomy it is assumed that there are no facilities for irradiation available. As to the choice of waiting a month or performing a hysterectomy, a decision must naturally be made in each individual case. This would depend on the clinical examinations. In doubtful cases, waiting is certainly preferable. A diathermy loop is an excellent way of performing biopsy for suspected carcinoma of the cervix. A knife is perfectly satisfactory if the procedure is executed carefully. There is no acceptable evidence that after the use of cautery the lymph flow is to the wound and that after the use of the knife it is away from the wound. Careful dilation of the cervical canal may be performed in cases of suspected carcinoma of the cervix without danger.

PULMONARY ACTINOMYCOSIS

To the Editor:—At present we have in our children's pavilion a 5 year old white boy who has pulmonary actinomycosis, proved by culture of pus obtained by aspiration. Could you give us any information as to the value of sulfanilamide or sulfapyridine or of iodides with or without thymol? What about surgical treatment; e.g., drainage or lobectomy or pneumonectomy? Any information or references would be appreciated.

Samuel A. Jaffe, M. D., New Haven, Conn.

ANSWER.—There is no undisputed evidence to show the specific beneficial effect of any of the drugs mentioned. The use of iodine salts is, of course, traditional. A few patients have been treated with thymol (Myers, H. B.: *THE JOURNAL*, May 29, 1937, p. 1875) and two with sulfanilamide (Miller, E. M., and Fell, E. H., *ibid.*, Feb. 25, 1939, p. 731. Hall, W. E. B., *ibid.*, May 27, p. 2190), all with apparently good results, but conclusions drawn from such limited experiences can be only suggestive. Surgical removal of infected material, when possible, and the curettage and evacuation of dead tissue in the visceral forms have also given good results (Wangenstein, O. H.: *Ann. Surg.* 104:752 [Oct.] 1936). Drainage, lobectomy and pneumonectomy would therefore seem to be worth trying, provided the infection is localized. General symptomatic treatment such as that practiced for the treatment of tuberculosis is of great importance.

CALCANEAL SPURS

To the Editor:—Can you give me any information concerning the injection method with sodium morrhuate for calcaneal spurs? M.D., Arizona.

ANSWER.—Many substances have been used as injection material to give relief from painful heels. Some of these patients have calcaneal spurs, others have not. An important consideration is the relationship of calcaneal bursitis to painful heels. Many of the patients who complain of painful heels have calcaneal bursitis. There is no doubt that the injection has relieved many patients; in some cases it has made them worse. One must realize that any injection in and around the periosteum of a bone is apt to cause considerable pain. Many of the patients who have been relieved by injection therapy have been relieved by the interfiltration of the spur bearing area, in which area there may be a bursa.

DANGERS OF MERCURIC OXYCYANIDE

To the Editor:—Is there any danger of absorption of mercuric oxycyanide through the skin? I use it in the strength of 1:1,000 and frequently pick up instruments without having my rubber gloves on. Is there any danger from the vapor that arises from this solution? M.D., Idaho.

ANSWER.—Mercuric oxycyanide is described in New and Nonofficial Remedies as "a basic-mercuric salt of hydrocyanic acid, containing from 51.7 to 56.0 per cent of mercuric cyanide [$\text{Hg}(\text{CN})_2$] and from 44.3 to 48.0 per cent of mercuric oxide (HgO). It is generally used in strengths of from 1:500 to as high as 1:10,000. If taken internally, the product is naturally toxic. The substance has been used as an antiseptic and in the treatment of syphilis more frequently in the past than in the present. Severe acute intoxications have been reported following its use in irrigating sinuses and hollow viscera. In general, it appears that the prospects of cutaneous absorption of mercuric oxycyanide are no greater than for many other mercury compounds widely used for disinfectant purposes. The small quantities of vapors that may arise from a solution of mercuric oxycyanide seem to be without significance.

INTERSTITIAL KERATITIS AND TRAUMA

To the Editor:—A patient had a foreign body embedded in the cornea for three days. The foreign body was removed and a small area of keratitis developed about the site of the foreign body. Within a few days an interstitial keratitis developed and the patient was found to have a 4 plus Wassermann reaction. Is it not probable that the foreign body excited a latent interstitial keratitis? Cannot an irritating substance cause a flare-up of a latent interstitial keratitis in a syphilitic patient? M.D., New York.

ANSWER.—This question raises one of the most interesting and unanswerable medicolegal problems. It is a well known fact that a comparatively minor trauma may be the exciting factor of a typical syphilitic interstitial keratitis and it is equally well known that the majority of cases of interstitial keratitis develop without the history of any preceding trauma. This question is discussed at length, with bibliography and citation of cases, in "Injuries of the Eye" by H. V. Würdemann, second edition, published by C. V. Mosby Company in 1932, page 433. According to various authors, anywhere from 3 to 20 per cent of all cases are precipitated by trauma, which may be of such minor nature as merely the instillation of irritating drops. But since practically all cases of interstitial keratitis are bilateral and the supposedly exciting trauma is usually monocular, the importance of injury as an etiologic factor must be denied. Furthermore, there is no evidence that the disease would not have developed without the trauma.

PRESCRIPTION MIXTURES

To the Editor:—Would there be any objection to the mixture of elixir of sodium thiocyanate with aromatic fluidextract of cascara sagrada and of elixir of sodium thiocyanate with elixir of phenobarbital? Would such a mixture be stable? C. L. Attaway, M.D., Villa Platte, La.

ANSWER.—The elixir of sodium thiocyanate and the aromatic fluidextract of cascara sagrada will form a homogeneous mixture which will not precipitate and which is stable. The same is true of the mixture of the elixir of sodium thiocyanate and the elixir of phenobarbital.

A possible objection to the first mixture would be that there is a combination of a sedative and a laxative in fixed proportions. In cases in which the sodium thiocyanate might presumably be used three times a day, the administration of cascara sagrada might frequently be objectionable. This objection does not apply to the second mixture if small enough amounts of the elixir of phenobarbital are used so that the mixture is not too depressing.

ASTIGMATIC DIAL IN REFRACTIONS

To the Editor:—What is the opinion among ophthalmologists concerning the use and accuracy of the Robinson-Cohen slide in routine refraction, both as a subjective test and under a cycloplegic? M.D., Ohio

ANSWER.—The Robinson-Cohen slide is a refinement of the astigmatic dial that is used by a number of ophthalmologists. It requires the use of the projection type of visual testing apparatus and changing of the slide when it is used. It is one of the most desirable methods of using the astigmatic dial and in the hands of a careful worker, is a useful addition to the refractive equipment. Many refractionists will not take the necessary time to make it useful. It is to be used, of course, in conjunction with other means of testing.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, Nov. 4, page 1757.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: *Basic Science*. Tucson, Dec. 19. Sec., Dr. Robert L. Nugent, University of Arizona, Tucson.

CALIFORNIA: *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California). San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: *Medical (Regular)*. Examination. Hartford, Nov. 14-15. *Endorsement*. Hartford, Nov. 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Medical (Homeopathic)*. Derby, Nov. 14-15. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Examination*. Dover, July 9-11. *Reciprocity*. Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

FLORIDA: Jacksonville, Nov. 13-14. Sec., Dr. William M. Rowlett, Box 786, Tampa.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: *Basic Science*. Des Moines, Jan. 9. *Medical*. Des Moines, Dec. 4-6. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Capitol Bldg., Des Moines.

KANSAS: Topeka, Dec. 12-13. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Louisville, Dec. 5-7. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

MAINE: Portland, Nov. 14-15. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Regular*. Baltimore, Dec. 12-15. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic*. Baltimore, Dec. 12-13. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

NEBRASKA: Lincoln, Nov. 24-25. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEW HAMPSHIRE: Concord, March 14-15. Sec., Dr. T. P. Burroughs, State House, Concord.

NEW YORK: Albany, Buffalo, New York, Syracuse, Jan. 29-Feb. 1. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: *Reciprocity and Endorsement*. Raleigh, Dec. 11. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 2-5. Sec., Dr. G. M. Williamson, 44 1/2 S. Third St., Grand Forks.

OHIO: Columbus, Dec. 5-7. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: *Basic Science*. Portland, Feb. 24. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia, January. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, Department of Public Instruction, 358 Education Bldg., Harrisburg.

SOUTH CAROLINA: Columbia, Nov. 14. Sec., Dr. A. Earle Boozier, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, Jan. 16-17. Dir., Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TEXAS: Austin, Nov. 20-22. Sec., Dr. T. J. Crowe, 918-19-20 Mercantile Bldg., Dallas.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 13. Sec., Dr. J. W. Preston, 30 1/2 Franklin Road, Roanoke.

WISCONSIN: *Basic Science*. Milwaukee, Dec. 2. Sec., Professor Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical*. Madison, Jan. 9-11. Sec., Dr. E. C. Murphy, 314 E. Grand Ave., Eau Claire.

BOOK NOTICES

Jour. A. M.
Nov. 11, 1938

Altogether this work is to be recommended as an exhaustive, painstaking and thoughtful review of a subject of tremendous importance. It should serve to correct a considerable number of misconceptions regarding the statistical facts respecting results in the surgical treatment of gastric cancer.

Studies on the Changing Incidence of Peptic Ulcer of the Stomach and Duodenum. By Gunnar Alsted, M.D., Privat-docent at the University of Copenhagen, Copenhagen. With a preface by Professor E. Meulengracht. Cloth. Price, 10s. Pp. 148, with 12 illustrations. Copenhagen: Einar Munksgaard; London: Oxford University Press, 1939.

Book Notices

End-Results in the Treatment of Gastric Cancer: An Analytical Study and Statistical Survey of Sixty Years of Surgical Treatment. By Edward M. Livingston, B.Sc., M.D., Associate Visiting Surgeon, Bellevue Hospital, New York, and George T. Pack, B.Sc., M.D., F.A.C.S., Attending Surgeon, Memorial Hospital, New York City. With a foreword by Bowman C. Crowell, M.D., Associate Director, American College of Surgeons. Cloth. Price, \$3. Pp. 179, with 7 illustrations. New York & London: Paul B. Hoeber, Inc., 1939.

This book is a statistical survey and analytic study of the surgical treatment of cancer of the stomach. The history of the surgical attack on this dread condition, as it has been revealed in medical literature, is traced in detail from the first successful gastrectomy by Billroth in 1881. The previous history is briefly reviewed and the authors come quickly to a minute consideration of the Therapeutic Era, which began over a half century ago. The first "classic study of Welch" (1885) is reviewed, which contained the pessimistic summary that "no patients subjected to resection survived longer than a year and a half." Some of the later reports are then surveyed and, comparing reports, Livingston and Pack pose the arresting question: "How could there be but three five year survivals in the quarter century in so prominent an institution as the Johns Hopkins Hospital up to 1915, then a report from another clinic but a relatively few years thereafter, of 127 ten year survivals?"

This question they themselves then undertake to answer in an analysis of the various factors, frequently overlooked, that make the reports of a number of "cures" apparently so contradictory. Thus it is pointed out that the number of "cures" that can be reported depends on the number of total patients seen, on the number considered operable, on the number considered resectable, on the period elapsed since operation, on the completeness of follow-up and on the mortality rates from other causes than cancer as well as on the survival from gastric cancer itself. Since one or more of these factors may be vastly different in different experiences, the number of reported cures also will differ. These points are elaborated and illustrated statistically by Livingston and Pack in considerable detail and with great acumen, and they categorize what are the primary requisites for cancer survival statistics if they are to be meaningful. When various reports from different sources are tabulated in a consistent way, it is found that there is actually a close agreement between the results of various authors and that the outlook for patients who have a partial resection for gastric carcinoma, while surely not rosy, is vastly better than that exemplified in the first classic report of Welch and considerably better than is commonly assumed. More than 14,000 partial gastrectomies for gastric carcinoma reported in the literature are included in the review. A striking feature of the work is contained in a supplement of eighty-nine pages of charts, giving the statistical facts adduced in graphic form. These are admirably conceived and executed and should be useful for general lectures and public education. A second supplement of twelve pages gives in tabular form a review of the series studied and the main summary statistical facts of each. A third supplement lists a bibliography of 358 items. Curiously this does not list the last report of the experience of the Mayo Clinic by Balfour, (*Ann. Surg.* 105:733 [May] 1937) although certain statistics in the text and charts appear to have been obtained from this article. Apparently this is due to a clerical error.

Man Against Himself. By Karl A. Menninger. Cloth. Price, \$3.50. Pp. 485. New York: Harcourt, Brace & Company, 1938.

This is an interesting presentation which proposes to group all impulses toward self destruction and to endeavor to explain them by a single theory. The author makes no claim that the theory is proved; he brings forward a great many interesting and for the most part convincing examples in support of it. Briefly stated the theory is that, from the uterus to the grave life is a struggle between the will to live and the wish to die and that various manifestations of human conduct represent different types and degrees of compromise between these conflicting drives or compulsions. The self destructive instinct is resolved by the author into three components, the aggressive (wish to kill), the punitive (conscience) and the submissive (wish to be killed). He takes up first suicide in the ordinary sense, that is, destruction of his life by the individual himself through swift, dramatic and often apparently sudden and impulsive acts. That these are never sudden or impulsive but the logical solution of deep-seated personality problems is part of the thesis of the book. From suicide he proceeds to a consideration of "chronic suicide," under which he deals with asceticism, martyrdom, re-

rotic invalidism, alcohol addiction, antisocial behavior and psychoses. He regards these as somewhat more successful though highly unsatisfactory solutions of personality conflicts. Next he considers focal suicide, under which he classifies self mutilations, malingering, addiction to surgery, purposive accidents, impotence and frigidity. Proceeding farther along the same line he analyzes organic suicide, in which he presents evidence, admittedly incomplete and fragmentary, in support of his conception that the psychologic factor in organic disease is far greater than is commonly recognized. In this connection the author presents a discussion of the totality concept in medicine and a brief consideration of the lesser evil as a more or less unsatisfactory compromise between the will to live and the wish to die. In diagrammatic form this is represented as the span from the uterus to the grave blocked by a black obstruction marked "external reality." In health this obstruction is completely avoided by a long elliptic detour labeled "normal excursion of life," composed largely of self-preservative impulses with a small component of self-destructive impulses. A shorter course skirting closer to the barrier but still avoiding it is labeled "neuroses" and is more heavily tintured with self-destructive impulses. A still shorter curve colliding directly with "external reality" is labeled "psychoses" and has a heavy preponderance of self-destructive impulses. The shortest course of all, composed entirely of self-destructive impulses, is labeled "suicide" and represents almost a direct line from the uterus to the grave. An exactly similar diagram is presented in which the life curves are labeled respectively "health," "hysterical lesions," "structural lesions" and "fatal processes." The first diagram is representative of psychiatric categories, the second of medical categories.

The book is an intensely interesting and logical exposition of a theory. The theory is, of course, predicated on the acceptance of psychoanalysis, to which the author is so completely committed that he regards its rejection as an example of stupidity, stubbornness or neuroticism. The book is one that no doctor, in view of the increasing interest in psychosomatic medicine, can afford to ignore. It appears to be published for lay readers, but despite its interesting style and its wealth of illustrative cases from medical literature, newspapers and news magazines it will make difficult reading for one who has not previously gained a conception of the workings of the human mind and a reasonable familiarity with the theory of psychosis.

Sulphonamide Treatment of Experimental Tuberculosis in Guinea Pigs. By Konrad Birkhaug, M.Sc., M.D. A Lecture Delivered at the Chr. Michelsen Institute's Annual Meeting, March 14, 1939. Paper. Pp. 59, with 7 illustrations. Bergen: A. S. John Griegs Boktrykkeri, 1939.

No medical institute worthy of the name exists which has not been intrigued by the possibilities of research with the drug sulfanilamide or its derivatives. In fact, not since the epoch-making discovery of Ehrlich has a new chemotherapeutic agent received such universal scientific recognition as sulfanilamide. Dr. Konrad Birkhaug in his lecture delivered at the annual meeting of the Christian Michelsen Institute, Bergen (March 14, 1939), reviews much of the work which has already been covered in the enormous medical archives of the past three years. In his lecture he reviews the chemistry of the various compounds. He states: "Happily, this cumbersome chemical name has been abbreviated by the Council on Pharmacy and Chemistry of the American Medical Association to sulfanilamide." In his lecture he pays particular attention to the work on sulfanilamide as outlined by Marshall, Emerson and Cutting and discusses thoroughly the dosage and chemotherapeutic range of the product. He also reviews rather extensively the treatment of experimental tuberculosis with sulfanilamide and concludes that prolonged sulfanilamide treatment in vivo failed to exert any attenuating action on the virulence, tuberculinogenesis, growth, cultural or tinctorial characteristics of the tubercle bacillus. He also reports that in the case of prontosil soluble there was some inhibitory action probably due to bacteriostatic effect which renders the virulent tubercle bacillus temporarily impotent but that the huge dose of prontosil soluble required to bring about this indirect effect makes it obvious that this form of sulfanilamide therapy falls short of representing the ultimate goal in the chemotherapy of clinical tuberculosis.

Relation of Trauma to New Growths: Medico-Legal Aspects. By R. J. Behan, M.D., Dr. Med., F.A.C.S., Surgeon, St. Joseph's Hospital and Dispensary, Pittsburgh. Cloth. Price, \$5. Pp. 425. Baltimore: Williams & Wilkins Company, 1939.

The author has accomplished a comprehensive review of a subject which is greatly in need of clarification. His approach to the problem is orderly. Following introductory references to historical aspects of the relation of trauma to cancer, the first chapters cover general phases of the subject, notable among which are those in reference to a classification of trauma and to the single trauma and aggravation controversies. This division of the book is concluded by an excellent presentation of the postulates which must be given consideration in determining the causative relationships between a malignant growth and previous injury. The remainder of the volume represents individual reviews of cancer in relation to occupation, medicolegal proof that trauma is the etiologic factor in a particular instance, and malignant disease following trauma involving various anatomic structures and systems, all of which are well developed. The work as a whole constitutes an excellent source of reference for the expert medical witness. Because of the extension of interest in the field of industrial disease and the relation of trauma to various pathologic states, this book should prove timely.

Handbuch der Viruskrankheiten mit besonderer Berücksichtigung ihrer experimentellen Erforschung. Unter Mitarbeit von K. Beller et al. Herausgegeben von Prof. Dr. E. Gildemeister, Vizepräsident des Instituts Robert Koch, Berlin, Prof. Dr. E. Haagen, Abteilungsleiter am Institut Robert Koch, und Prof. Dr. O. Waldmann, Direktor der Staatl. Forschungsanstalten, Insel Riems bei Greifswald. In zwei Bänden. Band II. Paper. Price, 44 marks. Pp. 768, with 105 illustrations. Jena: Gustav Fischer, 1939.

This book was written by the authors with the collaboration of thirty other investigators. The chapters are divided under seven headings: virus diseases with specific localization, virus diseases of cold blooded animals, virus diseases of insects, virus diseases of plants, viruses and tumors, diseases with virus-like agents and diseases of questionable virus etiology. Many chapters are concerned with animal diseases caused by viruses. The virus diseases with specific localizations are subdivided into three groups: (a) diseases of the respiratory tract, comprising nine chapters, one devoted to psittacosis, one to influenza, one to the common cold and the others to animal diseases, (b) diseases of the nervous system, comprising thirteen chapters treating such diseases as poliomyelitis, encephalitis and rabies, (c) diseases of other organs, treated in six chapters and including such diseases as venereal lymphogranuloma, molluscum contagiosum, and epidemic parotitis. Under the heading of diseases with virus-like agents are eight chapters in which such diseases as typhus fever and trachoma are discussed. A chapter on bacteriophage is also included under this heading. The second volume, like the first, is beautifully illustrated and the chapters are each followed by excellent bibliographies. This volume can be heartily recommended to research workers interested in virus diseases and also as a reference work to the physician interested in these diseases.

The Complete Guide to Bust Culture. By A. F. Nlemoeller, A.B., M.A., B.S. With a foreword by Edward Podolsky, M.D. Cloth. Price, \$3.50. Pp. 160, with illustrations. New York: Harvest House, 1939.

The reader who chooses this book because of its title is likely to be disappointed. Starting with the first chapter, which serves as the introduction to the subject, and continuing for 160 pages to the twenty-fourth chapter, which discusses diseases of the breast, one hopes in vain for some effective method that will develop the bust and will not be just a makeshift or an appliance that gives the illusion of a well developed bust. The chapters on physiology and anatomy are well written in simple language and give excellent information to the reader. In the chapters on exercise the author warns the reader at the beginning not to expect exercises to "do the impossible." He states that exercise will "do what it can as surely and dependably as any method in existence." The exercises he advocates are simple exercises that aim to bring about a better posture and are well known to most persons. The influence that diet has on the bust is told in the first paragraph of the chapter and the patient is warned that the breasts react the same as does any other part of the body in that it is not possible to feed a particular portion and ignore the rest. He warns against freak diets, sudden loss of weight in the obese and the too rapid gain of weight for the

very thin woman. The author neatly sums up the effects of creams and lotions on the bust by saying that the claim that such products can either "enlarge or reduce the breasts is utterly ridiculous." Of most value to the reader will be the chapters on brassières. The author discusses adequately the function of a brassière and describes the type that can be employed for the various types of busts. The final two chapters should have been omitted, as advice about actual treatment for various disease conditions of the breast is outlined. The warning that the physician needs to be consulted occurs only when potent drugs may be found to be necessary. Such advice as "liquids are restricted" and "cathartics administered," as well as "cautious massage" and "the breast pump should be employed," should not be left to the discretion of the patient. The discriminating reader will find some good information in this volume but must discount some parts as not being useful information for her.

Health and Unemployment: Some Studies of Their Relationships. By Leonard C. Marsh, Director of Social Research, McGill University, Montreal. In collaboration with A. Grant Fleming, Professor of Public Health and Preventive Medicine, McGill University, Montreal, and C. F. Blackler. Published for McGill University. Cloth. Price, \$3. Pp. 243, with 36 illustrations. New York: Oxford University Press, 1938.

The relationship of health to unemployment has been developed in the United States to a political issue. The authors realize, as they point out in their preface, that one question which must be considered side by side with the provision of medical care is that of nutrition. They say that, even if the network of medical nursing and hospital services is radically widened from its present coverage through health insurance, the doctor is still limited in his work by the physique and environment of his patients. The authors are convinced apparently that a national system of health insurance is fundamental to every other type of medical problem, and they have apparently accepted the statements by Falk as the basis for their conclusions.

Man Against Microbe. By Joseph W. Bigger, Sc.D., M.D., F.R.C.P.I., Professor of Bacteriology and Preventive Medicine, Trinity College, University of Dublin. Cloth. Price, \$2.50. Pp. 304, with 17 illustrations. New York: Macmillan Company, 1939.

There are good microbes and bad ones. The bad ones are those which bring about disease in human beings and animals. The good ones are those which participate in agriculture and industry. In this simple and well written book the author first discusses the nature of bacteria, next bacteria as a cause of disease, and finally control of food supplies, clean air and other sanitary problems. His book includes also brief sketches of the great contributors to bacteriologic science. It is a useful book, particularly for boys and girls of college age who have a special interest in this subject.

Health Officers' Manual: General Information Regarding the Administrative and Technical Problems of the Health Officer. By J. C. Geiger, M.D., Dr. P.H., Sc.D., Director, Department of Public Health, City and County of San Francisco, California. Cloth. Price, \$1.50. Pp. 148, with 12 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

From his wide experience in public health, Dr. Geiger has prepared the manual dealing briefly with general principles of public health and organization. All details of controversial subjects are omitted. Dr. Geiger's knowledge and organizing ability show clearly in the type of book which he has prepared.

The introductory material concerning organization should be a helpful guide to the health officer in the establishment of basic services. Under records and statistics are included birth and death registration, collection of material for statistical study, graphic presentation and the explanation of procedures generally used in morbidity and mortality records. Under medical services are included programs on child hygiene, public health nursing, dental hygiene, mental hygiene and nutrition. The communicable diseases are classified according to control measures applied. It is advocated that medical services rendered by the health department include an emergency service, hospitalization facilities and homes for children, the aged and incapacitated persons. The inspection and control services consider procedures in food inspection and control, housing inspection, industrial hygiene, camp sites and laboratories. The manual is well written, is easily read and should serve as a useful guide to health officers in the administration of a balanced public health program. While

primarily intended for those actively engaged in public health activities, this manual could be read with interest by the average lay person and would give him, in not too complicated form, a sufficiently comprehensive idea of modern trends in public health.

The Physiology of Exercise: A Textbook for Students of Physical Education. By James Huff McCurdy, A.M., M.D., M.P.E., Research Worker (Herbert L. Pratt Research Fellowship), 1935—, and Leonard A. Larson, B.A., B.P.E., M.Ed., Professor of Health and Physical Education in Springfield College (Corporate Title, International Young Men's Christian Association College), Springfield, Massachusetts, 1933—. Third edition. Cloth. Price, \$3.75. Pp. 349, with 3 illustrations. Philadelphia: Lea & Febiger, 1939.

The first edition of this book was published some years ago. The authors have made considerable revision and added a section on exercise for people over 40 and another on exercise for women. They have availed themselves of a large amount of research recently published and also of the personal advice of many of the leaders in the field of physiology of exercise. Each of the chapters is supplied with an adequate bibliography. The book is of the utmost importance as a guide to all of those who work in association with modern athletics.

Discovery of the Elements. By Mary Elvira Weeks, Associate Professor of Chemistry at the University of Kansas, Lawrence, Kansas. Fourth edition. Cloth. Price, \$3.50. Pp. 470, with illustrations collected by F. B. Dains, Professor of Chemistry at the University of Kansas, Easton, Pa.: Journal of Chemical Education, 1939.

The history of chemistry has been told in many ways. Here in brief form is the history of the discovery of each of the elementary substances with profuse illustrations and with brief biographical sketches of many of the noted chemists who contributed to the advancement of chemical science. The book is completed with a chronologic table and contains also a good index.

Nursing Through the Years. By Corinne Johnson Kern. Cloth. Price, \$2.50. Pp. 340. New York: E. P. Dutton & Co., Inc., 1939.

The author of this book has written two previous volumes, entitled "I Go Nursing" and "I Was a Probationer." She is apparently much impressed with her life as a nurse, and she fills her book of reminiscences with innumerable anecdotes from the time she began nursing in 1900 to the present period, when she lives in the mountains and even here finds opportunity for her skill and her work. She writes with some facility; her book should be interesting to the great public, which is just beginning to find out the trials and tribulations of all those who work in the medical field.

Nobel Prize Winners. Charts, Indexes, Sketches. Compiled by Flora Kaplan. Boards. Price, \$1.53. Pp. 60, with 2 illustrations. Chicago, Illinois: The Author, 1939.

In 1938 there was printed in Sweden a book on "The Nobel Prizes and Their Founder Alfred Nobel," by Fritz Henriksen (THE JOURNAL, Aug. 19, 1939, p. 711). Now there becomes available a pamphlet entitled "Nobel Prize Winners," compiled by Flora Kaplan and dedicated to Jane Addams. This includes also a brief sketch of Alfred Nobel, a copy of his will, a complete table of Nobel prize winners from 1901 to 1938 with reclassification by nationality and with brief biographic sketches of Nobel prize winners in each of the various categories. There are also special analyses of Nobel prize winners by nationality, sex, race and religion. Both these pamphlets are exceedingly useful sources of reference on this most interesting topic.

Treatment in General Practice: The Management of Some Major Medical Disorders. Volumes I and II. First American edition. Cloth. Price, \$7.50 per set. Pp. 259, with 6 illustrations; 436, with 8 illustrations. Boston: Little, Brown & Company, 1939.

The articles contained in these books were written as a series published by the *British Medical Journal* with a view to bringing general practitioners up to date on medical treatment. The books were published in Great Britain during 1936 and republished in 1938. They are introduced to the American medical profession by Dr. Reginald Fitz. The articles are succinct and practical but, obviously, not wholly up to date, as indicated by the fact that sulfapyridine is not even mentioned in the discussion of the treatment of pneumonia. There are

also references to medicinal products which are chiefly British and which are hardly known by their British names in this country. For instance, in one place readers are told to purchase their rubber mattresses from the Dunlop Rubber Company in England and other material useful in allergy from another British company. Throughout, indeed, all of the references are to British agencies. Thus the book is not nearly as useful as it would have been if it had been revised for American readers with new American work in mind. Nevertheless any general practitioner will find here innumerable practical hints of value in the daily practice of medicine.

Benjamin Franklin Calls on the President. By John de Meyer. Cloth. Price, \$1.25. Pp. 90. New York: Ives Washburn, Inc., 1939.

In this little satire the author has conceived that Benjamin Franklin rose from his grave on the 149th anniversary of his death and went to visit the President. It is the kind of humor that appeared in the book called "A Connecticut Yankee in King Arthur's Court." Benjamin Franklin comes in contact with the modern motor car, the shower bath, modern credit and debt, and the New Deal. It is interesting to find what the author thinks Benjamin Franklin would have said about spending oneself back into prosperity.

Hospital Dietetics as a Career. The Institute for Research, Research No. 41. Paper. Price, \$1. No pagination, with 3 illustrations. Chicago, Illinois: Institute for Research, 1939.

This twenty-four page illustrated booklet is designed to present adequately the calling of hospital dietetics as a career. It is readable and complete. It should be helpful to every person interested in becoming a dietitian.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Revocation of License for Allegedly Prescribing Narcotics to Satisfy Addiction.—The Colorado state board of medical examiners revoked the appellant's license to practice medicine on the basis of a charge that he was guilty of grossly negligent or ignorant malpractice and of immoral, unprofessional or dishonorable conduct. The district court of the city and county of Denver affirmed the revocation order and the physician prosecuted a writ of error in the Supreme Court of Colorado.

In brief, the physician was charged with writing various prescriptions of morphine for several named persons purportedly for the treatment of specified diseases when in fact the morphine was prescribed to satisfy narcotic addiction. The evidence showed that the morphine was prescribed in the quantities and to the persons named in the charge but, said the Supreme Court, there was no evidence in the record that the persons named were not suffering from the particular diseases specified on the prescriptions. The medical practice act authorizes the board to revoke a license to practice medicine if the physician has been convicted of a felony or of a crime involving moral turpitude or is "guilty of grossly negligent or ignorant malpractice" or of "immoral, unprofessional or dishonorable conduct." A conviction in a United States court on a charge of selling morphine to a habitual user thereof for other than medicinal purposes, the court said, is a conviction of a crime involving moral turpitude and warrants revocation of the physician's license. *White v. Board of Medical Examiners*, 70 Colo. 50, 197 P. 564. The physician in the present case, however, had not been so convicted. The board apparently proceeded on the assumption that it was sufficient if it found from evidence before it that there was a violation of the federal narcotic laws by the physician and reasoned that if a conviction of such violation in a court of competent jurisdiction carries with it the inference of moral turpitude as a matter of law, a finding by the board of such a violation has a similar effect. Such an assumption, the court said, was erroneous. The

board in a proceeding of this kind, until a conviction is shown, has no concern with the provisions of the Harrison Narcotic Act nor with the regulations promulgated thereunder. The board is not vested with jurisdiction to try alleged offenders for a violation of the act and may not make its own finding of such violation and predicate thereon either malpractice or immoral, unprofessional or dishonorable conduct. Acts that are inhibited by the Harrison Narcotic Act may be considered by the board where there has been no conviction, but such acts must be proved by competent evidence to constitute malpractice or immoral, unprofessional or dishonorable conduct, without regard to the violation of any law that inhibits them.

Treatment that is proper by correct medical standards does not constitute malpractice even though some law is violated. Malpractice consists of a failure to exercise that degree of care and skill in diagnosis or treatment which may reasonably be expected from one licensed and holding himself out as a physician, under the circumstances of the particular case. In the present case there was no expert testimony tending to prove a failure properly to diagnose or to treat the disease of the various persons with respect to whom malpractice was charged. It was not enough that the board may be composed of experts who applied their knowledge of diagnosis and treatment to the case. The medical practice act provides for a review by the district court in revocation proceedings and on such review the court may determine whether the board regularly pursued its authority or abused its discretion. Such determination can be made only on the evidence appearing in the record. Obviously the reviewing court cannot be left to speculate on what was in the minds of the individual board members.

Neither the regulations promulgated by the Commissioner of Narcotics, the Colorado narcotic act nor the Harrison Narcotic Act purport to limit the purpose for which or quantity of any drug that may be prescribed in good faith by a physician in treating a patient in the practice of his profession, and there was no evidence that the morphine prescribed by the physician in this case was not prescribed in good faith. The amounts prescribed and the frequency of prescriptions might be such that in and of itself it would indicate to one skilled in their proper use that a physician could not possess ordinary skill and in good faith so frequently prescribe such quantities. Such matters, however, being only within the knowledge of experts, must be shown by the testimony of experts appearing in the record. There was no such testimony in the present case.

It was charged that several of the prescriptions issued by the physician were not given in good faith but for the satisfaction of the patient's addiction, contrary to the federal narcotic laws. If that is true, the court said, there is a forum in which the guilt or innocence of the offender may be determined. If convicted in such forum, the physician's license may be revoked. But, until such conviction, the propriety of prescribing for such a purpose is to be determined not by the board asking and answering the question as to whether some statute or regulation issued pursuant thereto has been violated but by asking and answering the question as to whether, aside from any law or regulation, the diagnosis and treatment was such as a physician possessed of ordinary skill in the exercise of ordinary care in applying his skill with the object of promoting the patient's physical well being might make and prescribe.

The finding of the board was further to the effect that all the acts charged against the physician constituted not only malpractice but also immoral, unprofessional and dishonorable conduct. It appeared, the court observed, that the physician kept full records and had never failed or refused to make them available to officers entrusted with enforcing the narcotic laws. No member of the medical profession testified that the acts were outside the limits within which skilled and honorable men exercising ordinary care might operate in the practice of their profession. No recognized canons of ethics were shown by the evidence to have been violated, even if that were a matter for the board's consideration. In *Sapero v. State Board*, 90 Colo. 568, 11 P. (2d) 555, it was held that a mere violation of canons of ethics not amounting to a breach

of legal duty does not constitute a sufficient ground for the revocation of a license. Since in the present case all the acts relied on as constituting immoral, unprofessional or dishonorable conduct related to patients of the physician and to his manner of treatment, in the absence of evidence showing what a physician of reasonable and ordinary skill, applying it with ordinary care in the diagnosis and treatment of the patient involved, would have done, or should have done, the record furnished no factual standard for the board's conclusion and no standard for the court to determine whether the acts charged amounted to a breach of the legal duty which the physician owed to his patient and to society in the practice of his profession.

The judgment upholding the revocation order was therefore reversed and the trial court was directed to refer the matter back to the board of medical examiners for such further proceedings, if any, as it might deem advisable.—*McKay v. State Board of Medical Examiners (Colo.)*, 86 P. (2d) 232.

Accident Insurance: Death Due to Hypersusceptibility to Novocaine Not Death by "Accidental Means."—Preparatory to the performance of a tonsillectomy on the insured, novocaine (procaine hydrochloride) was administered hypodermically, infiltrating the tissue about her tonsils. Before "the usual amount" had been injected, her pulse weakened, she became pale, her body began to show a bluish cast, her breath became irregular and she died within a few minutes. Death was attributed to the patient's "hypersusceptibility" or "hypersensitivity" to novocaine. The plaintiff, as the beneficiary under insurance policies on the life of the deceased, sued two insurance companies on the policies. Those policies provided certain benefits in case of death due to bodily injuries caused solely by external, violent and accidental means. From a judgment in favor of the plaintiff, the insurance companies appealed to the Supreme Court of Appeals of West Virginia.

The principal question involved was whether or not death resulted from "accidental means." The plaintiff contended that if the use of novocaine resulted in something unforeseen and unexpected, the death resulted through accidental means even though the novocaine was injected intentionally and with the consent of the insured. The court admitted that the means employed by the physician produced unusual and unexpected results but refused to hold that the means by which they were produced were accidental. The physician did exactly what he intended to do and the patient invited it and therefore consented. The court thought that it could not be said that under such circumstances the means employed were accidental, even though the result was not one which was contemplated or expected and was due to an unknown and rare hypersusceptibility. The "means" employed were intentional, not accidental. In the opinion of the court the death did not come within the provisions of the policies sued on.

The judgments in favor of the plaintiff were reversed and new trials ordered.—*Oley v. John Hancock Mut. Life Ins. Co.; Same v. Educators Beneficial Ass'n (W. Va.)*, 199 S. E. 596.

Cosmetology: Services as "Professional Services"—Negligence as "Malpractice."—The defendant insurance company agreed to indemnify Herzberg's, Inc., a department store, against claims arising out of accidental bodily injuries occurring within the store. The policy, however, contained an endorsement which excepted the insurer from liability for—

bodily injuries, illness, or death resulting therefrom, suffered . . . in consequence of an error or alleged error or mistake in administering, applying or dispensing drugs, chemicals, mixtures or the like; or in the making or compounding of prescriptions; or in consequence of professional services or treatments or the omission thereof, or malpractice on the part of any physician, surgeon, nurse, druggist, assistant, attendant or any person connected with the Assured in the operation of the business covered by this policy.

A customer underwent a procedure in one of the departments of the store designed to remove superfluous hair, which procedure was administered by a so-called cosmetician, using an electrical apparatus called a "Tricho" machine. The customer was injured and subsequently sued the store, recovering judgment. The insurer refused apparently to pay either the judgment or the cost of defending the suit, and the store sued it

on the policy, recovering judgment in the district court of the United States for the district of Nebraska. The insurance company then appealed to the circuit court of appeals, eighth circuit.

The trial court, said the circuit court of appeals, apparently considered that the endorsement excepting the insurer from liability was confined to instances in which injury was "suffered in consequence of professional treatments administered by any physician, surgeon, nurse, druggist, or by any assistant, attendant or helper to any such physician, surgeon, nurse or druggist." Such a construction of the endorsement is too narrow. The endorsement provided, among other things, that the insurance company should not be liable for bodily injuries suffered by any person in consequence of professional services or treatments or malpractice, on the part of any attendant, person or persons connected with the assured in the operation of the business covered by the policy. The treatment of the customer's face for the removal of superfluous hair was a professional treatment administered in a department of the store by persons connected with the assured in the operation of its business. The department was held out to the public as qualified to administer treatments of the nature employed in beauty shops generally. The operator of the shop and her assistant were educated in schools devoted to instruction in the "art" of cosmetology.

It is significant in this connection that Nebraska has undertaken to regulate the practice of cosmetology by enacting a statute requiring certain educational and moral qualifications of persons licensed to practice cosmetology and authorizing the revocation of such licenses for the commission of malpractice and unprofessional conduct. The term "profession" in the past has been so generally associated with theology, medicine and law that the construction adopted by the trial court may be readily understood, but the term has long ceased to be restricted exclusively to those so-called learned professions. The term is defined in the New Century Dictionary, 1927, as follows:

Formerly theology, law and medicine were specially known as the professions; but as the application of science and learning are extended to other departments of affairs, other vocations also receive the name.

In the Oxford English Dictionary, 1926-1932, a "profession" is defined as

. . . the occupation which one professes to be skilled in and to follow [which involves a] vocation in which a professed knowledge of some department of learning or science is used in his application to the affairs of others, or in the practice of an art founded upon it.

The fact, continued the court, that physicians, surgeons, nurses and druggists are specifically mentioned in the endorsement does not limit its application to such professions and vocations. The obvious error involved in the professional application of the Tricho apparatus, whether due to negligence or ignorance, amounted to malpractice under the terms of this endorsement. Consequently, the insurance company is not liable under the policy.

The judgment below in favor of the department store was reversed.—*Ocean Accident & Guarantee Corporation, Inc., v. Herzberg's, Inc.*, 100 F. (2d) 171.

COMING MEETINGS

- American Academy of Pediatrics, Cincinnati, November 16-18. Dr. Clifford G. Grulee, 636 Church Street, Evanston, Ill., Secretary.
- American Society of Anesthetists, Los Angeles, Dec. 14. Dr. Paul M. Wood, 745 Fifth Ave., New York, Secretary.
- American Society of Tropical Medicine, Memphis, Tenn., Nov. 21-24. Dr. E. Harold Hinman, Wilson Dam, Ala., Secretary.
- Radiological Society of North America, Atlanta, Ga., Dec. 11-15. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse, N. Y., Secretary.
- Society for the Study of Asthma and Allied Conditions, Philadelphia, Dec. 9. Dr. W. C. Spain, 116 East 53d St., New York, Secretary.
- Society of American Bacteriologists, New Haven, Conn., Dec. 28-30. Dr. I. L. Baldwin, Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.
- Southern Medical Association, Memphis, Tenn., Nov. 21-24. Mr. C. P. Loranz, Empire Bldg., Birmingham, Ala., Secretary.
- Southern Surgical Association, Augusta, Ga., Dec. 5-7. Dr. E. Allen Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Western Surgical Association, Los Angeles, Dec. 15-16. Dr. Albert H. Montgomery, 122 South Michigan Blvd., Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

9: 69-104 (Sept.) 1939

Reducing Pneumonia Death Rate. G. S. Bryan, Amory, Miss.—p. 69.
*New Technic for Blood Sedimentation Test. C. Brooks, New Orleans.—p. 72.

Sulfapyridine: Its Use in Pneumococcal Infections. H. Kennedy and J. S. Smith, Birmingham.—p. 73.

Acute Purulent Pericarditis: Report of Case. J. O. Finney and J. O. Morgan, Gadsden.—p. 81.

New Technic for Blood Sedimentation Test.—Brooks outlines a blood sedimentation test which he believes is not difficult or complex in its performance and therefore its use should not be restricted. The method consists of filling a pipet with blood directly from the vein and setting the tube immediately in the vertical position in a holder. The graduated limb of the pipet is filled with anticoagulant, all of which is blown out except the thin film adherent to the inside of the tube. The graduated limb is then filled by inserting the needle into a vein and permitting the blood to flow into the tube by its own pressure. As soon as the tube is filled just beyond the 100 mm. mark, the cock is closed, cutting off the lumen exactly at the 100 mm. mark; the column of blood held in the tube is thus exactly 100 mm. long. The needle is quickly removed and the tube is immediately put in the vertical position in a holder. The sedimentation is observed for an hour or longer and the results are recorded on a chart. The method is simple, automatic, direct and precise. Its employment should encourage a wider use of the blood sedimentation test.

Epidemiology of Syphilis in New York City. T. Rosenthal and J. Weinstein, New York.—p. 1034.

Scarlet Fever in Negroes.—Cornely discusses the supposed differences in the mortality and morbidity rate from scarlet fever in the white and Negro populations in the South, which has led to the belief that this disease is not common in the Negro and that therefore he is highly resistant to it. This resistance has been attributed to his resistant ectoderm and to a longer racial experience. These two explanations do not seem to hold true when the author's data are considered, which show that although there are great differences in the South there is little inequality in the northern cities in the mortality and morbidity rates from scarlet fever in the two races. If the Negro was highly resistant to this disease, even though his mortality and morbidity in the North and South might not be similar, the disparity between the two races would be just as great in the North as in the South. This the author states has not been shown in his data. Secondly, the idea of racial susceptibility must be discarded when

the results of Dick test surveys of several investigators have shown that there is no significant difference between reactions of white and Negro children to this test. The recorded low mortality and morbidity from scarlet fever in Negroes in the South may be explained on (1) the occurrence of mild and sub-clinical cases which are not recognized and not reported and (2) most of all on the poor reporting of typical cases and deaths in the rural areas of the South, in which almost 70 per cent of the southern Negroes are to be found. That mild and atypical cases of scarlet fever must occur widely in the South draws support from the results of Dick test surveys made in certain tropical countries, which have shown the higher prevalence of negative Dick tests and the earlier appearance of this immunity in children in the tropics. No differences were found between Negroes and white persons. Mayer and Davison have similarly shown that, although in North Carolina the number of cases reported was less than half that in New York City, the rate of susceptibility was much lower than that found in various other comparable groups in the United States. Thus, it must be assumed that there is a wide prevalence of mild and atypical cases in the South.

Error in Counting Bacilli in Sputum. W. N. Berg, New York.—p. 351.

Collapse Therapy of Tuberculosis.—Hruby reviews the history of the institution of collapse therapy for tuberculosis and its value in the control of the disease in a community, in particular Chicago. Over the six and a half years since the procedure has been carried out in the Municipal Tuberculosis Sanitarium he states that the results in 7,341 cases have been twice as good in the cases so treated as in the controls. Undue attention must not be paid to the mortality tables as an index to the value of collapse. To be fully effective, collapse as a measure of community control of tuberculosis should have widespread and efficient application. Wherever possible the unified plan should prevail, intramural collapse, extramural collapse, reciprocity of function, interchange of patients as between the sanatorium and the field. For the fullest measure of community control this combination is necessary. The field clinic, expensible, inexpensive, elastic in its applicability to the need, should take up the treatment immediately after the patient is dismissed from the sanatorium. The much discussed question of the initial treatment outside the Municipal Tuberculosis Sanitarium does not seem to make a great difference, 70.6 per cent of the patients who received their initial treatment in the clinic are living as against 78.1 per cent for the patients who received their first injection in the Municipal Tuberculosis Sanitarium. The figures embracing 3,090 treated cases explode the belief still current in some quarters that the induction of collapse is purely an institutional prerogative. Owing to its possibilities in the direction of community control, collapse in the Negro deserves more energetic consideration. At present the results for Negroes, while not as good as those for white persons, are considered satisfactory. A gap in the mortality of six to one is reduced to a gap of three to two. The officers and medical personnel of the Municipal Tuberculosis Sanitarium engaged in the study are convinced that collapse, in its dual capacity as public health instrument and medium of cure, symbolizes a union of ends and aims, offering the patient his best chance and the community its best protection.

Traumatic Subcutaneous Rupture of Normal Spleen.—

Wright and Prigot report the thirty cases of subcutaneous rupture of the normal spleen due to trauma observed at the Harlem Hospital from Jan. 1 to Sept. 1, 1938. Operation or necropsy proved that the spleen was the injured organ in these cases and histologic section showed normal splenic tissue. Nine of the patients were from 5 to 10 years of age. Of these, eight were injured in automobile accidents and the ninth by a fall against the curbstone. In the age group from 11 to 20 years there were five patients, of whom only two were struck by automobiles, one was injured while riding in an automobile, one was struck by a bicycle and one was injured while coasting. Alcohol played a prominent part in the injuries of seven patients from 21 to 30 years of age. Three were hurt by falling while drunk, one was involved in an automobile accident while inebriated, two were injured by automobiles and one either fell or jumped from a fourth story window. Two of six patients between 31 and 40 years of age were victims of assault and battery, three were involved in automobile accidents and one fell and injured himself while under the influence of liquor. There were three patients from 43 to 61 years of age and two of these were injured by automobiles and the cause of injury to the third was undetermined. Seven of the thirty patients were women. The diagnosis of subcutaneous rupture of the normal spleen is not easy. There are no signs or symptoms pathognomonic of this condition; therefore each case must be considered on its own merit. The symptoms and signs of rupture of the spleen are chiefly those of local injury and hemorrhage, shock and peritoneal and diaphragmatic irritation. Abdominal pain is the most common complaint. This pain is usually sharp and lancinating and is localized in the left upper quadrant. However, it may be described as generalized abdominal soreness and is sometimes more acute in the other quadrants. All the patients either entered with this symptom or had it while under observation. The symptom next in order of frequency is dyspnea. Eight of the patients complained of being "short winded" or had some form of respiratory distress. Vomiting occurred in three and diarrhea in two. In all cases there were abdominal tenderness and spasm. The trauma which produces the splenic injury may cause contusion of the abdominal wall. In no case were there any external marks on either the abdomen or the back. The erythrocyte count and the value for hemoglobin may be normal, but in all except one case in the series the latter was low, ranging from 40 to 80 per cent. The erythrocyte count ranged from 2,400,000 to 4,400,000 per cubic millimeter. The leukocyte count ranged from 6,000 to 23,850 per cubic millimeter and not infrequently failed to rise with increasing temperatures. The abdominal tap has proved to be of invaluable aid in the diagnosis of subcutaneous injury of the abdominal viscera. If the result is negative but the patient continues to show signs of concealed hemorrhage, it should be repeated. The differential diagnosis must exclude lesions above the diaphragm and retroperitoneal as well as intra-abdominal conditions. The diagnosis is most frequently missed because a history of trauma is not obtained or, if one is obtained, it is

disregarded. Associated lesions may mask the signs and symptoms associated with a ruptured spleen. The treatment of rupture of the spleen is surgical, that is splenectomy. Pre-operative enemas are forbidden. The mortality (thirteen of the thirty patients died, a gross mortality of 43.3 per cent, and seven died without operation, giving an operative mortality of 27.3 per cent) for subcutaneous rupture of the normal spleen is discussed. This mortality the authors believe can be lowered by (1) constant alertness on the part of the surgeon and the staff to avoid errors in diagnosis, (2) more rapid diagnosis so that the patient will receive the benefits of operation sooner, (3) use of a slow blood drip preoperatively with or without intravenous administration of fluids (when blood from a "bank" is not readily available, infusions of a saline solution should be given) and (4) adequate fluids should be given to restore water balance.

Effect of Overactivity and Disuse on Joint Cartilage.

—Freund discusses the behavior of cartilage under ultraphysiologic conditions (increased pressure) and infraphysiologic conditions (disuse). He finds that functional stimuli below or above the physiologic optimum, if active over a long period, are deleterious to joint cartilage. The damage does not remain limited to the joint cartilage in growing persons but draws the bony epiphysis into participation by stopping further endochondral ossification. The time factor is of greatest importance in the development of pathologic changes in the joint cartilages. The pressure force may stay within normal limits; nevertheless, it will damage the joint cartilage if it is continuously active over a long period. The same is true of disuse. Too little or too much use of joint cartilage over a long period is detrimental. This is confirmed by almost every day's operative and necropsy material and does not need proof by animal experimentation. With genu valgum or genu varum, for instance, typically hypertrophic arthritic changes develop in older age. Marginal exostoses and degeneration and fibrillation of joint cartilage will be present at the condyles with increased weight bearing, while atrophy and retraction of joint cartilage are noticed in the condyles with less weight bearing. Whether the pressure force is intense and working over a relatively short period or whether it is within physiologic limits but of protracted or continuous action, the result will be the same: the joint cartilage will lose its normal elasticity and will suffer irreparable damage. With the loss of elasticity, the ways are opened for the different processes of cartilage degeneration, even for reactive resorption from below by bone marrow—all changes preceding and accompanying hypertrophic arthritis. Any definite alteration of function for a long period (infraphysiologic and ultraphysiologic demands) is certain to lead to degenerative changes of joint cartilage and may be followed by the whole syndrome of fully developed arthritis deformans, the more probably the longer the joint is exposed to unphysiologic use.

Gonadotropic Substance in Gynecology.—Hall used equine gonadotropic substance in 135 cases of various gynecologic disorders. Of the patients with menstrual disturbances 57.6 per cent were cured, 47 per cent of those with genital hypoplasia were cured and twenty-four of the forty-three (55.8 per cent) who were treated for sterility became pregnant. A number of the patients necessarily fall into more than one group. For example, a patient whose primary complaint was sterility may also have had associated dysmenorrhea or hypomenorrhea, and one who complained of the subjective symptoms of estrogenic deficiency might also have had genital hypoplasia, dysmenorrhea or oligomenorrhea.

Effect of Prolactin on Mammary Secretion.—The nursing history and breast secretion of 380 consecutive nursing mothers were recorded by Stewart and Pratt for the first ten postpartum days. Of the 380 mothers, 333 nursed their babies; 207 were full-breast nursing, seventy were part-time nursing and fifty-six deficient nursing. Of the fifty-six deficient lactating mothers only twenty-four expressed their desire to nurse the baby for at least six weeks, to receive injections of prolactin in an attempt to improve the milk supply and to pump the breasts every four hours for a minimum of five days (from the fifth to the ninth postpartum day). Ampules of identical appearance containing 5 cc. of solution to be injected daily were differentiated by the labels 68A and 60A. The contents of these ampules remained unknown until the study was concluded. After the results were tabulated, it was learned that ampules 68A contained 1,000 pigeon units (Riddle) of lactogenic hormone. Ampules 60A contained no hormone. In addition to the deficiency cases, ten part-time nursing mothers were studied. The average daily milk secretion of 184 cc. on the fifth postpartum day of fourteen deficient mothers receiving prolactin increased to 212 cc. the following day. There was a decrease in seven of the fourteen cases on the seventh day, the average output falling to 205 cc. From the seventh to the ninth day there was a progressive increase to 258 cc. The average total gain during the entire period was 74 cc. In relation to the amount secreted on the fifth day, this represents a gain of 40 per cent. In three women the milk production was less on the ninth than on the fifth day. None of this group were discharged with full-breast nursing. Ten mothers receiving the control solution showed a gradual rise from an average breast secretion of 219 cc. on the fifth day to 311 cc. on the ninth day. The total average gain during this period was 92 cc., or 42 per cent. In two the amount of milk produced on the ninth was less than on the fifth day. No mother in this group was discharged with full-breast nursing. The average gain of primipara and multipara was 88 cc. (42 per cent) and 81 cc. (44 per cent) respectively. In the ten women in whom the breasts were pumped every four hours and the baby did not nurse, the average gain was 71 cc., or 43 per cent. In fourteen the breasts were pumped immediately after the baby nursed; in these the average gain in milk secretion was 89 cc., or 39 per cent. The average secretion on the fifth day of fourteen mothers less than 30 years of age was 215 cc. It increased to 325 cc. on the ninth day. In ten mothers more than 30 years of age the average output on the fifth day was 176 cc. On the ninth day it was 227 cc. All twenty-four deficiency cases were seen at the end of six weeks. Ten mothers in the prolactin and control groups had dried up the breasts because of insufficient milk supply. Those who had received prolactin showed no significant increase of milk secretion over the control group. Part-time nursing mothers whose milk production on the fifth day was more than 300 cc. produced a greater average increase of milk secretion than the deficiency group. This series averaged 341 cc. on the fifth day and showed a progressive daily rise to 450 cc. on the

ninth day. The total average increase of 109 cc. was greater than either the control or prolactin cases in the deficiency group. The percentage increase, however, was less (31 per cent). Multiparas showed a greater increase than primiparas. The two mothers in this group discharged with full-breast nursing were multiparas.

Blood Epinephrine After Insulin Hypoglycemia and Metrazol.—Heilbrunn and Liebert determined the activity of epinephrine and epinephrine-like substances in the blood serum in patients during various hypoglycemic states. The curves of those patients evidencing shock showed an inadequate adrenal response to insulin ninety minutes after the injection, while the nonshock curves displayed a marked rise in the epinephrine level of the blood at this time. The epinephrine output of a third group was dependent on the muscular movements; this was confirmed by observations on the epinephrine level of the blood serum after metrazol convulsions. The epinephrine level reflected directly the various stages of insulin hypoglycemia. At the time of deep coma the epinephrine level was low, while it rose to a high level at the time of recovery.

Vitamin D and Serum Phosphatase in Arthritis.—Smith and his co-workers determined the serum phosphatase activity after prolonged medication with vitamin D in cases of atrophic and hypertrophic arthritis and concluded from their study that serum phosphatase activity does not promise to be of value as a diagnostic aid in arthritis as there is a wide distribution of values above, below and within the normal range. The possibility of its value as an aid in differentiating between the atrophic and hypertrophic types is again negated by the wide distribution, regardless of the somewhat higher average that was obtained in a limited number of hypertrophic cases. Also there is a possibility that the shift in the serum phosphatase activity, observed to occur in patients who have ultimately benefited from vitamin D, might prove to constitute a basis for prediction as to the suitability of such therapy. Further investigation is needed.

Metabolism of Normal Individuals in New Orleans.—As a practical result of comparing the four commonly used standards for determining the metabolic rates in ninety-eight women and sixty-two men (apparently normal students and staff of the Louisiana State University) Eaton arrived at a set of corrections which may be applied to existing standards in predicting the basal heat production of individuals in New Orleans and, it is hoped, in other parts of the deep South. He proposes to employ a correction factor of —10 per cent to all

values of the Aub and Du Bois standards or — 11 per cent for men and — 7 per cent for women to the recent Mayo Foundation standards. These corrections are shown to be valid statistically. The cause of the lowered basal metabolic rate in warm climates has been discussed by many investigators. It is a fact that metabolism is somewhat proportional to the average annual temperature, although the relationship cannot as yet be expressed as a linear function. Lessened desire for strenuous physical exertion and greater ability and desire for relaxation must be considered as probable factors in lowering the metabolic rate. Whatever the cause may be, the lowered basal heat production lessens the strain on the heat-eliminating mechanism and makes life more comfortable in a subtropical climate, especially during hot humid nights, when heat is so difficult to dissipate. The mechanism by which this adaptation is brought about is as yet obscure.

Hormones in Pregnancy.—Siegler presents the quantitative determination of the total estrogenic and chorionic gonadotropic hormones in five normal pregnancies and in one case of toxemia of pregnancy, which toxemia was alleviated by the administration of large doses of estradiol benzoate. An average gradual increase in the total estrogenic hormone eliminated was observed in the five normal cases of pregnancy, from 3,500 rat units per liter of urine on the thirtieth day following the first missed menstrual period, reaching a peak at term of 82,000 rat units, after which there was an abrupt decline of the concentration of the total estrogenic hormone to 2,200 rat units on the first postpartum day to 200 rat units on the fourth postpartum day. The lowest amount excreted on the thirtieth day was 1,800 and the highest 4,800 rat units. The lowest concentration at term was 70,000 and the highest 100,000 rat units. Conversely, in the determination of the chorionic gonadotropic hormone there was a sudden increase from 7,500 mouse units per liter on the fourteenth day after the first missed menstrual period to its peak of 140,000 mouse units on about the thirtieth day. Thereafter there was an abrupt decline, with a level below 10,000 mouse units after the sixtieth day to an average of about 4,500 mouse units to the termination of pregnancy, becoming negative on the fourth postpartum day. The lowest concentration in the first two weeks following the first missed menstrual period was 4,500 and the highest was 15,000 mouse units. The lowest amount at the peak was 96,000 and the highest was 210,000 mouse units. In the several instances in which the serum had been used in the assaying of the total estrogenic and gonadotropic hormones, the amounts estimated coincided with those found in the urine. The hormone determination in the case of toxemia of pregnancy showed a rise in the amount of gonadotropic hormone in the fifth and sixth months. An increase in blood pressure, the presence of albuminuria and edema in the following month with a higher level of gonadotropic hormone concentration, and a subnormal amount of total estrogenic hormone followed. These higher levels persisted with the severe toxemic symptoms until estradiol benzoate was given. Following this the level of gonadotropic hormone fell to almost normal, the level of the total estrogenic hormone rose in amount and the toxemic symptoms subsided.

Sodium Diphenyl Hydantoin for Epilepsy.—Weaver and his associates used sodium 5, 5-diphenyl hydantoin in the treatment of fourteen epileptic patients, who received the drug for periods of from two weeks to three months. Eight of the patients have been definitely benefited, six of them especially so. The results in the other six have proved so adverse that it was necessary to discontinue the treatment. Nine of the patients had a diminution in the number of their convulsions; two had a reduction in the severity of their convulsions. The general mental condition of six improved. There was a definite improvement in the postconvulsive state in three of the patients. A marked improvement in personality ensued in two. The numerous psychotic episodes disappeared in one patient who had had them. Two patients made gains in weight. One patient developed a rather unusual—certainly for her—state of well being. The two patients who were most improved were receiving phenobarbital in addition to the other drug. This suggests synergistic action. As to the unfavorable results, six patients were extremely drowsy for from two to six weeks after medication with the drug. Three suffered profound psychic distress. Three had an increase in the number of their seizures. Three complained of persistent and severe headache. A severe cutaneous reaction developed in five patients; in two of these this was complicated by edema of the face. These reactions disappeared on temporary withdrawal of the drug (though in two cases there was a later recurrence). One patient, who had been having only a few grand mal convulsions a month, began to have frequent and numerous petit mal convulsions. One patient who had never before been incontinent became so after receiving the drug for several weeks. One patient had an acute abdominal crisis that simulated acute appendicitis. One patient had a severe gastritis and diarrhea. Loss of appetite occurred in two. It is a powerful drug and appears to be more toxic and dangerous than phenobarbital. In their opinion the patient receiving the drug should be under the physician's constant observation. In the cases that were benefited the improvement was not solely a diminution in the frequency and a lessening in the severity of the seizures (that could quite probably have been brought about by massive doses of phenobarbital, bromides or chloral) but in several cases a rather remarkable improvement in the patient's personality, behavior and mental alertness occurred. The drug should be regarded as valuable for the treatment of convulsive disorders.

Acute and Subacute Necrotic Myelitis.—Greenfield and Turner report three cases of necrotic myelitis and assert that clinically the cases of necrotic myelitis fall into two distinct groups: the acute group, which they illustrate by one case, and a subacute group, represented by the original two cases. Acute necrotic myelitis shows itself by a rapid destruction of function of the spinal cord in the lumbar and sacral segments, with, at least in their case, a fairly rapid ascent of the signs to the lower dorsal segments. Owing to the rapidity of disturbance of function of the cord a flaccid paraplegia develops, and in none of the recorded cases has there been any sign of recovery from this. In the subacute type the disease is of gradual onset and slowly progressive course, usually without any remission, though in one case there was some recovery of power in the legs for from two to three months. The presenting symptom is usually weakness of the legs, though this may be preceded by severe pain in the distribution of the sacral segments or by dysesthesia in the lumbar and sacral areas. The differential diagnosis of acute necrotic myelitis presents considerable difficulty. While syphilitic transverse myelitis may be excluded by a negative Wassermann reaction, other types of acute myelitis, especially those due to the demyelinating diseases, are likely to cause confusion. The demonstration of a spinal subarachnoid block is the most valuable distinguishing feature between cases of spinal compression due to epidural abscess or Pott's disease and those of acute necrotic myelitis. In the differential diagnosis of subacute necrotic myelitis both amyotrophic lateral sclerosis and subacute combined degeneration may cause some difficulty in the early stages of the disease, but the development of sphincter disturbance and sensory changes will soon exclude the former, and the absence of dysesthesia in the hands and the normal blood count and gastric analysis the latter. Chronic meningovascular syphilis affecting the lumbosacral cord has to be excluded. The most difficult differential diagnosis is the differentiation from extramedullary or intramedullary tumors in the lumbosacral region of the cord. The two main differential points are the frequent occurrence of root pains and pain in the back in extramedullary tumors, and gradual ascent of the sensory level, which is usual in cases of subacute necrotic myelitis and rare in cases of tumor. The presence of subarachnoid block at lumbar puncture will settle the diagnosis, since tumors at this level are invariably associated with some degree of spinal block. Pathologically necrotic myelitis consists essentially of primary obliterative sclerosis of the small intramedullary and meningeal vessels in the lower segments of the spinal cord and is associated with great thickening of the walls of the larger meningeal veins and sometimes also of the larger arteries. The degeneration of the parenchyma of the spinal cord appears to be altogether secondary to the vascular lesion.

Freshness in Relation to Environment.—According to Bedford and Warner the requirements for a pleasant and invigorating environment can be stated: 1. A room should be as cool as is compatible with comfort, since freshness tends to increase as the temperature is reduced. 2. There should be adequate air movement. During the winter season the air velocity in the ordinary factory averages about 30 feet per minute and in the majority of cases lies between 20 and 40 feet per minute. At velocities much below 20 feet per minute feelings of stuffiness are likely to arise. In summer weather or in hot factories velocities rather higher than those mentioned are desirable. 3. The air movement should be variable rather than uniform and monotonous. The body is stimulated by ceaseless change in the environment. Outdoors one is braced by the changing play of the wind, and likewise the variations of air movement which may be encountered indoors exert an invigorating effect. When ventilation is obtained through open windows the air movement is likely to be variable, but with some mechanical ventilating systems the air movement is undesirably monotonous. In mechanical installations the air inlets should be so designed and the velocity of discharge so arranged that suitable eddying currents are set up. 4. The relative humidity of the air should be kept reasonably low. It should not exceed 70 per cent and should preferably be much below that value. 5. The average temperature of the walls and other solid surroundings should not be appreciably lower than that of the air and should rather be warmer. The combination of cold walls and warm air often causes a feeling of stuffiness. 6. The air at head level should not be distinctly warmer than that near the floor, and the heads of the occupants should not be exposed to excessive radiant heat. 7. The air should be free from objectionable odors.

Weil-Felix Reaction in Trachoma.—Various workers in different countries claim that in serums from patients with trachoma a positive Weil-Felix reaction is found and regard this as evidence that the causal agent of trachoma is a Rickettsia. Kirk and his colleagues therefore examined 200 serums from Sudanese patients with trachoma and state that the study failed to reveal any significant differences with regard to the Weil-Felix reaction between them and twenty-two serums from non-trachomatous controls or 1,000 serums taken, without reference to trachoma, from a large and representative section of the population. Clinical and serologic evidence suggests that typhus is absent from the Sudan. For this reason the interpretation of results is less liable to confusion in the Sudan than in countries in which positive Weil-Felix reactions may occur in a varying proportion of the population, owing to typhus infections.

Dermatitis of Laundresses.—In a review of the literature on the "dermatitis of laundresses" Rabeau and Ukrainczyk show that especial attention has been directed to the important part played by alkaline substances in the pathogenesis of occupational dermatitides. Alkaline substances produce an alteration of the epidermis which in turn predisposes to sensitization. Thus soaps have not only an irritating but also probably an eczematogenic action. As a result of their dissolving effect on the fats of the skin, the alkaline substances prepare the way for sensitization. Experiments demonstrated that there are persons who are sensitive to alkaline substances and who lack the capacity to neutralize them when they are applied to their skin. This deficiency has been found in 8 per cent of normal subjects and in 90 per cent of patients with eczema. Some investigators believe that sodium hypochlorite can elicit allergic conditions and the authors determined that there is another important factor of sensitization, namely chromium compounds. In studies on the frequency of sensitivity for Javelle water, which is used widely in France for purposes of cleaning and disinfecting in households and for bleaching in various industries, the authors used cutaneous tests as well as a palpebral test. They found the palpebral test especially helpful in that it revealed sensitizations not detectable by the usual methods. The patient closes his eyes and a specimen of the substance to be tested is applied to one of the eyelids. The reaction is read after twenty-four hours. The authors describe studies on the eczematogenic power of the different substances used in laundering on patients sensitized to Javelle water and to bichromates. These studies demonstrated the absolute parallelism of these sensibilizations and the eczematogenic action. In studies and observations on different types of Javelle water it was observed that the sensitization apparently depends on the presence of bichromates. The authors gained the impression that the intolerance for chromium precedes that for chlorine. They were able to collect 200 patients presenting this double intolerance to chlorine and chromium. The following occupations were represented: housekeepers, employes of hotels and restaurants, laundresses, cement workers, mechanics, pharmacists and physicians; moreover, there were patients in whom the sensitization could be traced to cosmetics such as powders containing lead bichromate. It was found that solution of chlorinated soda and black soap are not tolerated by the patients with double sensitization. The authors think that this is due to the fact that solution of chlorinated soda is often wrongly prepared from Javelle water and a little Javelle water is occasionally added to black soap. They rarely observed chemical intolerance to substances other than bichromates and hypochlorites. They stress the social importance of the dermatitis produced by Javelle water, pointing out that they occur in different occupations and that they may be of long duration.

Amebiasis and Cancer of Large Intestine.—Cade and Milhaud demonstrate that from the diagnostic point of view the relations between cancer of the large intestine and amebiasis present three different aspects: (1) cancer can simulate amebic dysentery, (2) chronic amebiasis can assume a pseudocancerous form and (3) cancer and amebiasis may coexist. As regards the concurrence of amebiasis and cancer, the authors consider two possibilities: either cancer may appear sooner or later after amebic infestation or, in a patient with neoplasm, examination of the feces may reveal the pathogenic amebas of dysentery.

The authors describe two cases of association of amebiasis and cancer which illustrate these two eventualities. In one case the neoplasm was localized on the transverse colon, in the other case in the rectosigmoid. The authors show that an exact diagnosis is of great importance, since if cancer is present extensive and early excision is necessary. A reliable diagnosis will be derived from the results of rectal palpation, of roentgenologic examination and of rectosigmoidoscopy, complemented if possible by biopsy. Digital examination of the rectum permits the detection of indurated, irregular and perhaps painful masses. The hardness is generally greater in cancer than in amebiasis, as is also the adherence to the base and the tendency to bleeding. Nevertheless the tactile examination may be confusing, especially if the tumor is located high up. It is advisable to complement it by rectosigmoidoscopy. The latter procedure is indispensable if digital examination of the rectum is negative. If after rectoscopy there is still uncertainty, biopsy should be done. Roentgenoscopy is valuable particularly in cancers situated high up, which escape digital examination and even rectosigmoidoscopy. Trial treatment with emetine and arsenical substances may also furnish valuable information.

*Medical Treatment in Suppurative Nontuberculous Pleuritis. P. Lévy-Valensi, S. de Sèze and J. Pinès.—p. 1309.
Gas Masks and Correction of Ametropias. Cot, Moynier, Genaud and Robert.—p. 1311.

Suppurative Nontuberculous Pleuritis.—Lévy-Valensi and his associates treated five patients between 29 and 59 years of age who had high fever in consequence of streptococcal pleuritis, evidenced on puncture. Peroral dosage with carboxyl-sulfamidochrysoidin varied from eight tablets of 0.2 Gm. each administered daily to twelve (2.4 Gm.). Treatments lasted from seventeen days to six weeks with progressive determinations of increasing sterility. In two cases pachypleuritis was roentgenologically established at the time of discharge from the hospital. In their discussion of sulfonamide derivatives used in antibacterial chemotherapy the authors favor those belonging to the azo coloration group over the white because of their freedom from toxicity and accidents, especially in streptococcal pleuritis. The authors recommend early treatment with sufficiently high dosage from the beginning, according to the drug employed. Daily treatment should be continued until successive punctures show complete asepsis of the interpleural fluid and a negative culture response. They do not favor simultaneous peroral, intramuscular and intrapleural dosing with sulfonamide derivatives or serous and vaccinal therapy but recommend cardiac tonics and cardiovascular analeptics and systematically continued puncture tests. For precautionary purposes they advise that the patient be kept in bed for from eight to ten days after suspension of treatment, with resumption of dosing at one third strength for another week. Repeated clinical and x-ray examinations may indicate residual pachypleuritis. To overcome this an open air convalescence and breathing exercises methodically pursued are indicated.

Insulin Suppositories for Diabetic Patients.—Wuhmann directs attention to experiments with the rectal administration of insulin suppositories which Brahn and Langner reported in the *Nederlandsch Tijdschrift voor Geneeskunde* 83:3784 (July 29) 1939, abstracted in THE JOURNAL October 14, page 1525. In view of the possible practical significance of this rectal administration of insulin, Wuhmann decided to try it in cases of diabetes. He studied the blood sugar curves of fourteen diabetic patients and of four persons without metabolic disorders, following the rectal administration of insulin suppositories. The rectal administration of the insulin suppositories was combined with a sugar tolerance test, and the

blood sugar values were determined before and for a certain period after. More than fifty blood sugar curves of diabetic patients were studied and eleven of the persons who were free from metabolic disorders. Since the rectal administration of glandular preparations requires much larger doses than does the subcutaneous injection, the author designated 10 injection units as 1 suppository unit. Thus, a 20 unit insulin suppository contains 200 injection units. Since larger doses are required, the author thinks that less refined forms of insulin can be employed for rectal application, in that for instance the presence of protein substances does not constitute a hindrance in this form of administration. He reproduces only a few of the blood sugar curves which he obtained in the course of his studies. He reaches the conclusion that measurable and effective quantities of insulin can be introduced by means of rectal suppositories. However, he thinks that the extensive use of insulin suppositories in the practical therapy of diabetes mellitus will require further clinical investigation.

Occupational Manganese Intoxication in Steel Industry.—Reviewing the cases of manganese poisoning that have been reported in the literature, Voss demonstrates that, in comparison to the wide technical use of manganese and its compounds, the number of occupational manganese intoxications is small. As explanations for this the author suggests that apparently only a small number of persons have the predisposition for manganese poisoning, that not all manganese compounds are capable of exerting a toxic action in the organism, and that danger of occupational poisoning exists only where manganese or manganese compounds are inhaled or swallowed in adequate quantities and for a comparatively long period. Small quantities of manganese, such as are used in the ceramic industry in the preparation of lacquer and in the dye and glass industries, apparently are not sufficient to elicit chronic manganese intoxication. Impairments of the central nervous system by manganese have hitherto been observed in persons engaged in the mining of manganese ores, in the sorting and handling of ores containing manganese, in the processing of pyrolusite (manganese dioxide) and in those who come in contact with manganese vapors or who work with metallic manganese. In the steel industry manganese intoxications may be produced not only by manganese vapors but also by the dust of ferromanganese. The author reports the clinical history of a man, aged 33, who for ten months had worked part of the time and for seventeen months all of the time in a deficiently ventilated room, tending a number of ferromanganese grinders. For more than two years the man felt well, but after that the typical symptoms of manganism developed: masklike face, amyostatic symptoms, disturbances in speech and walk, micrographia, compulsory weeping and laughing, stuttering, and disturbances in the potentia coeundi. Moreover, there were mild polyglobulism and monocytosis. The increased manganese content of the feces, which was still manifest more than eight months after the man had ceased working with manganese, indicates that the patient's organism had stored manganese. That other men who worked under the same conditions did not develop manganism does not contradict the causal significance of manganese in the reported case because an individual predisposition seems to play a part. Since nervous lesions caused by manganese frequently remain constant or gradually increase, it is somewhat surprising that considerable improvement resulted in the reported case. However, other cases have been reported in which cessation of contact with manganese, on appearance of the first symptoms, was followed by great improvement or complete cure. The author points out that this case cannot be cited as proof of the toxicity of metallic manganese, because some oxidation takes place in the course of grinding and it is possible that products of oxidation exert the toxic action.

Vitamin K and Coagulation of Blood in Jaundice.—Koller and Wuhrmann show that the hemorrhagic tendency in obstructive jaundice, which is greatly feared by surgeons, has found an explanation in recent years. The favorable therapeutic effect of vitamin K in jaundice corroborates the assumption that a K avitaminosis exists. This is not surprising when it is considered that vitamin K is fat soluble and that fat resorption is impaired in obstructive jaundice. After reviewing the clinical history of one case in which vitamin K exerted a specific effect, the authors say that they were able to demonstrate the prompt action of vitamin K on the coagulation time and on the hemorrhagic diathesis in nine cases of obstructive jaundice (five cases of cholelithiasis and four cases of carcinoma of the pancreas or choledochus). They also state that analogous observations were reported by Danish and American authors. In hepatocellular icterus, especially cirrhosis of the liver, vitamin K seems to exert no effect, which suggests that the regenerating action of vitamin K on prothrombin presupposes a more or less intact function of the hepatic cells. However, the retardation in the coagulation which is observed in nontropical sprue can be promptly counteracted by vitamin K. In this connection the authors direct attention to the fact that Fanconi ascertained in 1928 that in infantile sprue (intestinal infantilism) there occurs a form of hemorrhagic diathesis in which C avitaminosis does not appear but in which a hypothrombinemia exists. The K avitaminosis in nontropical sprue is understandable when it is considered that a disturbance in resorption is an essential factor in this disease.

Hypnosis Therapy of Pruritus Cutaneus. N. G. Bezyuk.—p. 397.

Brucellosis.—Tarpi's observations on sixty patients treated at the Tropical Institute of Stalinbad (Tadjik Republic) between 1932 and 1936 revealed that forty-six presented a gradual onset, fourteen an acute onset, and that the undulant type of fever was observed in only eighteen cases. Among the characteristic symptoms were noted persistent fever, painful sensation in the bones and joints of arthralgic rather than of arthritic type, and the appearance of painful subcuticular nodes located, as a rule, on the upper third of the arm and on the digital phalanges. These persisted for from fifteen to thirty days. Pustular, papular and roseolar rashes were observed during the various stages of the disease. In 85 per cent of the cases there were profuse sweats. The spleen was enlarged in 41 per cent, the liver in 53 per cent and there was an orchitis in 18 per cent. A mild degree of hypochromic anemia with leukopenia (from 4,000 to 5,000) and lymphocytosis was the rule. In the cases in which a positive blood culture was obtained, *Brucella melitensis* was the organism found. The author was not able to differentiate, on the basis of clinical signs, maltase fever from Bang's disease. Diagnosis is best made by the blood culture method. It takes from twelve to twenty-one days to grow the organism. The allergic brucellin test was positive in all of his cases as well as in a number of the laboratory workers who had contact with laboratory animals. The coexistence of malaria had an aggravating effect on the course of brucellosis. The average duration of the disease was six months. There were no fatalities in this series. Metenamine, calcium, acri-

flavine hydrochloride, collargol, arsphenamine and ethoxy-diamino-acridine lactate did not prove to be of much therapeutic value. Autohemotherapy was without effect, whereas citrated blood transfusions were effective in the beginning of the disease. Vaccine prepared from avirulent strains of *Brucella suis* and given intravenously in increasing doses proved to be the most effective therapy in the series.

Removal of Corpus Luteum During Early Pregnancy.
—Duyvené de Wit and Oppers report a case in which the corpus luteum of pregnancy was removed on the eighty-third day after the last menstruation. From this time until the sixth month of pregnancy progesterone was administered. Unimpaired by occasional uterine contractions, the pregnancy took a normal course. The authors further cite reports from the literature, comprising 131 cases, in which the corpus luteum was removed during the first four months of pregnancy. A review of these cases discloses that in the absence of substitutional therapy abortion results in 23.7 per cent of the cases. With regard to the treatment, the authors take the following position: In ovariectomies during pregnancy, progesterone should be given prophylactically and for some weeks after the operation. If there are no threatening symptoms and a careful supervision is possible, an expectant attitude can be taken, because in three out of four cases the pregnancy will remain intact and take a normal course without substitutional therapy. A clear understanding of the progesterone exchange can be obtained only if it is determined how much progesterone exists at a certain time in the organs preparing it, in the blood, in the organs consuming it and in the products of excretion. In the case reported by the authors, Duyvené de Wit's bitterling test was employed for the determination of the progesterone content. The corpus luteum of pregnancy which was removed from the woman weighed 1.3 Gm. and it was found to contain 33 micrograms of progesterone per gram of tissue. This is about twice as much as is found in a mature menstrual corpus luteum. The placenta, which weighed 480 Gm., contained 640 micrograms of progesterone.

Roentgen Therapy in Nonspecific Chronic Arthritis.

—Bakke rapidly reviews various theories proposed to account for the beneficial effect of roentgen rays on nonspecific chronic arthritis and reports the results that he obtained in a serial roentgenographic examination of 555 persons. He regards primary calcareous deposits in the soft tissues surrounding the joints (chiefly shoulder, knee, loins and hip) as "catch basins" for infective matter released into the blood stream by lesions elsewhere, thus conditioning inflammation and pain, and attributes the beneficial effect of roentgen rays to their action on the inflammation set up in the capsular ligaments of the joints. The author was able to verify his theory of the significance of primary lime deposits by roentgenologically testing the soft

tissues of the shoulders of 200 persons ranging in age from 20 to 69 years who had never previously complained of pain in that part of their body and by discovering that twenty-six of these (13 per cent) showed larger or smaller calcium accumulations (three bilaterally). Of these twenty-six, the age group from 20 to 29 was represented by five cases. The 555 patients with nonspecific chronic arthritis roentgenographically examined included 230 male and 325 female subjects, the age level ranging from 20 to 89, with the greatest incidence in the ages between 30 and 70. Tests made were followed up with oral or written inquiries. Subsequently 523 were reexamined and divided into four groups with the following results: no change 11.9 per cent, improved 15.3 per cent, greatly improved 34.6 per cent and cured 38.4 per cent, irradiation thus benefiting 88.3 per cent in some way. The total number of actual cures, represented by 38.4 per cent, amounted to 213 cases (age level 40 to 49, sixty-two cures; age level 50 to 59, sixty-eight). Grouped according to the chief seat of the arthritic or periarthritic ailment, there were 170 shoulder cases with 103 cures, 148 knee cases with fifty-seven cures, 103 loin cases with twenty-seven cures and eighty-three hip cases with fifteen cures. The dose, adjusted to the nonresident character of the majority of the patients, was administered daily or at most every other day, the regular dose amounting to 100 roentgens per field. Every joint received serially four or six such doses, the series varying from one to four or five and in stubborn cases to eight, at intervals of from four to eight weeks. While the knee received 100 roentgens in the course of from four to seven days, the shoulders, loins and hips received 150 six times, the hand 100 four times and so on. The author's unit skin dose was about 750 roentgens. The analysis of failures indicated that unimproved patients received on an average 1.38 treatments compared with 2.14 for the others and seems to suggest the caution not to discontinue treatments prematurely.

Avitaminosis K in Infants and Hemorrhagic Diathesis.

—Dam and his associates say that in normal children an avitaminosis K, usually moderate, develops in the first days after birth and usually disappears after a week. This avitaminosis K causes a hypoprothrombinemia which must be regarded as the cause of the common slight hemorrhagic diathesis in the newborn. Whether or not jaundice is present seems to be without significance. The avitaminosis is assumed to be due to a deficient supply of vitamin K through the intestine. In some cases of icterus gravis of the newborn, anemia of the newborn and congenital dropsy, considerable hypoprothrombinemia was established. Since the administration of vitamin K in two of their cases was followed by a rapid rise in prothrombin, the authors conclude that there was an avitaminosis K in these cases. A complete lack of prothrombin established as early as twenty-four hours after birth is ascribed to reasons other than deficient resorption from the intestine.

SULFAPYRIDINE IN THE TREAT- MENT OF PNEUMONIA

NORMAN PLUMMER, M.D.

AND

HERBERT K. ENSWORTH, M.D.

NEW YORK

The only agent of proved value in the specific treatment of pneumonia heretofore has been antipneumococcus serum. While effective in many types of pneumococcal pneumonia, it has been costly, frequently unavailable, often tedious and occasionally impossible to give. The advent of sulfapyridine has given us another effective specific agent, and this time one that is comparatively inexpensive, more readily available and more easily administered.

During the year that has passed since Whitby¹ described experiments in which sulfapyridine afforded complete protection in mice against as high as 10,000 lethal doses of pneumococci, a large number of articles have appeared in the medical literature concerning the use of this new therapeutic agent.

On the experimental side, Fleming² has found that the drug retards the growth of pneumococci in human blood in concentrations as low as 3 mg. per hundred cubic centimeters. He³ subsequently demonstrated that the blood of patients taking sulfapyridine has a much increased antibacterial power against the pneumococcus. MacLean, Rogers and Fleming⁴ have shown that pneumococci vary in their sensitivity to the drug but that this variation is associated not with the type of pneumococcus but with the individual strain. Greey, MacLaren and Lucas⁵ have shown that sulfapyridine is superior to sulfanilamide, to a glucoside derivative of 4:4' diamino diphenyl sulfone (promin) and to hydroxyethyl-apocupreine dihydrochloride in pneumococcal infections in mice. Hilles and Schmidt⁶ have

reported that the drug is effective in experimental type XXII infections.

On the clinical side, reports have come from a variety of localities. In England, Evans and Gaisford⁷ used sulfapyridine in 100 cases of pneumonia with a mortality rate of 8 per cent. In a control series the mortality was 27 per cent. In India, Anderson and Dowdeswell⁸ in an alternated series of 100 cases observed a mortality rate of 16 per cent in the controls and 2 per cent in the treated. In South Africa, Agranat, Dreosti and Ordman,⁹ in a cooperative study embracing 550 cases of pneumonia, obtained either a marked reduction in mortality (in a general mine hospital) or a shorter period of pyrexia (in native mine hospitals). In Canada, Graham, Warner, Dauphinee and Dickson¹⁰ and Meakins and Hanson¹¹ have reported favorably on the drug.

In this country, Flippin, Lockwood, Pepper and Schwartz¹² in Philadelphia used sulfapyridine in a series of 100 cases of typed pneumococcal lobar pneumonia with a mortality rate of 4 per cent (excluding three cases under treatment twelve hours or less). A preliminary report has been published by us.¹³ Finland, Spring, Lowell and Brown¹⁴ have used sulfapyridine alone or in combination with serum in the treatment of 175 cases of pneumonia due to specific types of pneumococci, with good results. Encouraging reports concerning the use of the drug in childhood pneumonia have come from Barnett, Hartmann, Perley and Ruhoff¹⁵ in St. Louis, from Wilson and his associates¹⁶ in Cincinnati and from MacColl¹⁷ in Durham, N. C.

A summary of the replies to a questionnaire¹⁸ sent out by THE JOURNAL to approximately 100 physicians

The sulfapyridine and serum were supplied by the Lederle Laboratories, Inc.

This investigation has been conducted under a grant of the Josiah Macy Jr. Foundation.

Read before the Section on Pharmacology and Therapeutics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

working with sulfapyridine embodies experience with the drug in about 1,800 cases of pneumonia in adults and 650 in children. It is here stated: "While there is much to be learned about the exact place of sulfapyridine in the treatment of pneumonia, it appears to be a very useful measure in many cases when properly employed." Caution in its use is advised until more evidence of its usefulness and safety is available, and the necessity for continuation of typing is emphasized. Sulfapyridine has been accepted for inclusion in New and Nonofficial Remedies.¹⁹

Pharmacologic and toxic aspects have been covered by Wien,²⁰ Long,²¹ Marshall, Bratton and Litchfield,²² Johnston,²³ Stokinger,²⁴ Long, Bliss and Feinstone,²⁵ Cooper Gross and Lewis,²⁶ Schmidt and Hughes,²⁷ Hoyt and Levine,²⁸ Bryce and Climenko²⁹ and Sutherland.³⁰

That pneumococci can rapidly acquire tolerance or fastness to sulfapyridine has been demonstrated in laboratory animals³¹ and in man.³²

MATERIAL AND PROCEDURE

The present report deals with our experience and that of our associates with sulfapyridine at the New York Hospital and at Bellevue Hospital.³³ We have administered sulfapyridine to 270 patients suffering from pneumococcal pneumonia, either typical (lobar) or atypical.

As soon as the clinical diagnosis of pneumonia is made, sputum and blood are obtained for bacteriologic study and a blood count is taken; sulfapyridine therapy is then started immediately. In nearly every case one or more x-ray films of the chest are taken. Frequent urinalyses are done and blood counts are repeated.

Our routine order for sulfapyridine is for 2 Gm. as an initial dose, followed by 1 Gm. every four hours until 16 Gm. has been given. At this point it is decided whether the drug should be stopped or continued. Most of the patients need no more. Complicated cases, cases in which the response is inadequate and, in particular, the bacteremic cases are continued on the drug, usually at the 6 Gm. a day rate. A few patients have been given 0.5 Gm. every two hours. Occasionally, after the first course, the dose is increased to 1.5 or 2 Gm. or reduced to 0.5 Gm. every four hours. In some cases consider-

able help may be obtained from the level of free drug in the blood. For that determination we have used both the Marshall method³⁴ and that of Werner;³⁵ the latter has a short modification sufficiently accurate for clinical work. Rectal administration of the drug has been tried, but absorption is either quite small or lacking altogether.

RESPONSE

In a large majority of instances a marked fall in temperature and in pulse rate occurred within twenty-four hours, and many times this had already begun by the time the second dose of sulfapyridine had been given. Associated *pari passu* with these changes were

* Serum was used in addition in 102 of the cases, as follows: type I, 26; II, 9; III, 17; IV, 4; V, 10; VI, 1; VII, 10; VIII, 15; X, 1; XI, 1; XII, 1; XIV, 2; XVII, 1; XVIII, 1; XXIV, 1; XXV, 1; XXVIII, 1.
† Eleven of these were fatal within twenty-four hours of onset of therapy. Corrected mortality, 8.5 per cent.

a decrease in toxemia and a subjective improvement. Bacteremia—in some cases what appeared to be an overwhelming bacteremia—was usually promptly controlled, although the patients with bacteremia tended to have a moderate degree of fever for a week or more after the original fall in temperature. Not every bacteremic patient whose blood was sterilized recovered, however. The physical signs seem to go through the usual cycle.

The marked frequency with which the temperature falls in pneumococcal infections when sulfapyridine is given, together with the fact that in other infections in which we have used the drug such a fall is much less frequent or does not occur at all (e. g. staphylococcal empyema, non-pneumococcal pneumonia), leads us to believe that the temperature response is not merely an antipyretic effect.

We have been interested in finding out whether the use of sulfapyridine would interfere with the capsule of the pneumococcus and consequently with typing. Whitby² observed that when mice are injected intraperitoneally with pneumococci and then treated with sulfapyridine the capsule shows degenerative changes. rence,³⁷ reporting two cases, observed that the capsules of pneumococci recovered from the sputum of patients being treated with sulfapyridine failed to react with the type-specific serum with which they had originally reacted. We have not been able to confirm this finding. Repeat typings are done on our patients when the original typing has not shown a fixed type (I, II, V and VII). In a series of seventy-five such retypings, capsular swelling occurred whenever pneumococci were present, even after as much as 40 Gm. of drug had been given. Furthermore, there has been no interference with the capsules of pneumococci recovered from the blood, spinal fluid or pleural exudate after as much as 200 Gm. of sulfapyridine. There was one exception to this: poor capsular swelling in organisms recovered from the blood of a patient with bacteremia and endocarditis was observed after 140 Gm. of sulfapyridine had been given, but subsequent blood cultures typed easily, even though the drug was continued.

In a more recent article, McIntosh and Whitby³⁸ state that they have seen capsular degeneration only in peritoneal samples and believe that the nonencapsulated coccus found by Telling and Oliver was probably present simultaneously with the original type III coccus observed but persisted in the sputum after the other had disappeared. In this connection it should be kept in mind that the bacterial flora in the sputum often changes during the course of pneumonia whether any specific treatment is given or not.

EFFECT ON THE MORTALITY RATE

Of the 270 patients with pneumococcal pneumonia in our series, thirty-four (12.6 per cent) died. If eleven cases in which death occurred within twenty-four hours of the beginning of treatment are excluded, the rate becomes 8.5 per cent. The distribution by types is shown in table 1.

It is interesting that the mortality rate at Bellevue Hospital was 15.3 per cent (10.3 per cent if twenty-

the twenty-four hour group are excluded the mortality rate becomes 25.8 per cent. The distribution is shown in table 2.

In any evaluation of our statistics it must be borne in mind that, of the 270 patients with pneumococcal pneumonia treated with sulfapyridine, 102 were given

serum also. The patients in this series were not alternated between drug alone and drug and serum; we now have available serum for all types, and the problem of the value of serum in conjunction with sulfapyridine is now being studied at Bellevue Hospital in a cooperative program of the First, Second and Fourth medical divisions and involves strict alternation of cases. In the present series, generally speaking, serum was used for the more seriously ill patients. For example, of the thirty-five patients with bacteremia twenty-two received serum as well as sulfapyridine. It is therefore not possible to give an exact mortality rate on the basis of the present series either for sulfapyridine alone or for sulfapyridine plus serum.

However, the clinical recovery of a number of the patients seemed more rapid and certain when serum was used. At least from a theoretical point of view it would be rational to expect a surer response when the effect of the specific antibodies contained in serum is added to that of sulfapyridine, which apparently acts directly on the bacteria, probably by neutralization of some metabolic function or enzymatic activity,³⁹ and is not concerned with the immunity mechanism. It may be that the use of serum in conjunction with sulfapyridine will further reduce the low mortality rate, which, it appears, can be obtained with sulfapyridine alone. It will take some time to determine this, and until the question is determined we believe that the use of serum should not be abandoned.

BLOOD SULFAPYRIDINE LEVELS

There is a marked individual variation in absorption and acetylation of sulfapyridine. With our routine dosage we obtained blood levels of free drug ranging from traces to 25 mg. per hundred cubic centimeters.

Six patients had blood determinations made at hourly or two hourly intervals after the onset of therapy. Sulfapyridine was detected in the blood within an hour, rose steadily for about twelve hours and then began to level off. Subsequently the level in a given case usually remained fairly uniform as long as the same dosage was maintained. Increasing the dosage after this level increases the blood level, but not in proportion to the extra amount of drug given.

At what time after administration of a dose of sulfapyridine should blood be taken for determination of the blood level? In an effort to answer this we made hourly determinations in five cases and found that, once the initial period of rise mentioned is over, there is no significant variation in blood level between one dose and the next. Consequently we feel that blood may be taken at any convenient time.

Marshall and Long⁴⁰ have recently advocated the use of sodium sulfapyridine by vein when absorption of sulfapyridine from the gastrointestinal tract is poor, when prompt action of the drug is imperative or when patients are vomiting. Blake and Haviland⁴¹ have dis-

several cases in which there was no prompt response, increasing the dose had no appreciable effect on the clinical course. The cases in which this was tried, however, were complicated cases; two were severely bacteremic and one was a case of empyema.

TOXIC REACTIONS

The phase of the problem concerned with toxic reactions is of great importance, and careful attention has been given to it. Our data in this regard are based on the 270 cases of pneumococcal pneumonia and in addition fifteen cases of pneumonia in which we could isolate no pneumococci, five cases of subacute bacterial endo-

13. M. H.	75	Unclassified	5	0	Responded to drug; delirium caused transfer to psychiatric ward where sulfapyridine was not given; spread of pneumonia and death	29. E. W.	67	III	4	300,000	12 hr. case: blood pressure 210/80; known arteriosclerotic heart disease for 5 years
14. C. W.	45	III	17	350,000	Admitted 4th day with bacteremia, 100 colonies per cc.	30. R. M.	63	XIV	16	550,000	Admitted with uremia and bacteremia
15. A. G.	37	I	4	240,000	12 hr. case: admitted on 8th day with bacteremia	31. J. M.	63	IX and XVIII	10	0	Arteriosclerotic heart disease; sudden death after temperature normal several days
16. J. M.	81	XXIII, XXIV	15	0	Bacteremia type XXIII; did fairly well until drug was stopped through error	32. M. H.	69	VIII and streptococcus	75	0	Arteriosclerotic heart disease; probable cardiac death
						33. E. N.	17	VIII	50	100,000	Acute rheumatic fever with pneumonia
						34. R. M.	12	X	10	0	Acute rheumatic fever with pneumonia and bacteremia; died 40 hr. after admission

solved 2 Gm. of sulfapyridine in 1 liter of 5 per cent dextrose in saline solution by heating the solution nearly to boiling; this preparation may then be given intravenously or by hypodermoclysis.

CORRELATION OF BLOOD LEVEL WITH CLINICAL RESPONSES

Flippin and his associates found that good clinical responses occurred in cases in which the blood level was only from 1 to 2.8 mg. per hundred cubic centimeters and that there was no apparent correlation between the blood level and the rapidity of recovery. We likewise are unable to state what an "adequate" blood level might be. Some of the best responses that we have had occurred in the "lowest level" group. In

carditis and thirty-one miscellaneous cases. The incidence of the various reactions is given in table 3.

Nausea and vomiting is almost certainly central in origin. It rarely occurs until from 4 to 6 Gm. of sulfapyridine has been given, and it has been shown⁴⁰ that giving sodium sulfapyridine by vein causes vomiting. We have found no satisfactory way to control it short of allowing the blood level to fall. Here again, however, individuals vary greatly; some vomit when the blood level is only 2 or 3 mg. per hundred cubic centimeters and others do not vomit when the blood level reaches 8 or 9 mg. Usually the drug could be continued in spite of vomiting, which frequently lessens as recovery takes place.

Four of the five patients with morbilliform rash had received between 30 and 40 Gm. of drug; the other, 16 Gm. The rash cleared promptly when the sulfapyridine was stopped.

PNEUMONIA—PLUMMER AND ENSWORTH

1851

A number of patients had minor falls in red blood cell counts and hemoglobin values, such as might be encountered in severe infections. Only two, however, were severe enough to cause concern; in both the hemoglobin content fell below 50 per cent. Recovery followed withdrawal of the drug.

Liver damage attributable to sulfapyridine has not been encountered clinically or at autopsy. In our experience, toxic effects involving the kidney and ureter have been the most disturbing. In two cases, definite ureteral stones composed of sulfapyridine have been found. The first of these two patients was a woman of 40 with subacute bacterial endocarditis who received 540 Gm. of sulfapyridine over the course of three months. The blood levels ranged from 4 to 8 mg. per hundred cubic centimeters, and subjective and objective improvement occurred, but eventually she died. Microscopic hematuria was noted a few days before death. At autopsy two small white stones were found in the pelvis of one kidney which on analysis showed almost pure acetylated sulfapyridine. X-ray films were taken but they were found not to be radiopaque. There were healed kidney infarcts, but Dr.

festations and who recovered, and also in a man aged 54 with pneumococcal endocarditis after 200 Gm. of the drug had been given. With others, we believe that the explanation of hematuria as a toxic reaction is precipitation of the quite insoluble acetylsulfapyridine in the kidney tubules and pelvis and consequent mechanical damage. In the last case cited, however, it is uncertain

Chart 1.—Clinical course in case 1.

Jacob Furth, the pathologist, believes that the stones caused the hematuria in this case.

In the second case, one of type III pneumonia, gross hematuria and pain in the flanks radiating down the ureters occurred after only 13 Gm. of sulfapyridine had been given. Urographic study revealed negative shadows in the kidney pelves interpreted as stones, and cystoscopy was done. Gravel was found in the bladder and ureters; on analysis this proved to be composed of acetylated sulfapyridine.

Two other patients in our series had gross hematuria. One was a seven months pregnant woman with type III pneumonia who had severe bilateral ureteral colic and hematuria after 15 Gm. of sulfapyridine had been given. Urographic study was done. One kidney pelvis was dilated, but the head of the fetus overlay this abnormality, obscuring the plates and interfering with their interpretation. No stone was passed but recovery was prompt. The other patient was a man aged 55 with the grip. After the administration of only 5 Gm. of sulfapyridine, temporary anuria occurred, followed by gross hematuria and a rise in urea nitrogen to 37 mg. per hundred cubic centimeters. He recovered when the drug was stopped, and again no stones were passed.

Microscopic hematuria was noted after administration of 16 Gm. of the drug in a man aged 68 with type III pneumonia who had no other renal symptoms or mani-

Chart 2.—Clinical course in case 2.

whether the blood came from kidney infarcts or as the result of endocarditis or was due to sulfapyridine itself. At autopsy, no stones were found but infarction was present.

In three additional cases, temporary elevation of the blood urea nitrogen was observed without other signs of kidney damage. Sulfapyridine was discontinued and prompt recovery ensued.

Besides these cases in the present series, we have first hand knowledge of the occurrence of gross hematuria—in two instances in children—in five patients not under our care. Kidney stones have been produced with sulfapyridine experimentally by Antopol and Robinson⁴² and by Gross, Cooper and Lewis.⁴³ Lawrence⁴⁴ has reported a human case of hematuria

Chart 3.—Clinical course in case 3.

and renal colic due to stone, and Southworth and Cooke⁴⁵ reported three cases of hematuria, one with visible blood, in persons under treatment with sulfapyridine.

COMPLICATIONS

1. *Empyema*.—This was encountered thirteen times. In all but two cases, signs suggestive of fluid were present before therapy was begun.

2. *Otitis Media and Mastoiditis*.—One patient was admitted with this condition complicating a type VIII pneumonia.

3. *Pleural Effusion*.—Six sterile nonpurulent effusions occurred. All the patients recovered on repeated thoracentesis.

4. *Endocarditis and Meningitis*.—These conditions occurred once each, in the same case. It is interesting that in this case signs of meningitis and a positive spinal

fluid culture for type VII occurred three weeks after admission, but both subsequently cleared up on continued drug therapy. Recurrence was noted, however, when the patient was in a terminal state nearly three weeks later.

COMMENT ON THE FATAL CASES

The fatal cases are summarized in table 4. Eleven of the thirty-four patients died within twenty-four hours of the onset of therapy. Of the remaining, eight had serious organic disease affecting the cardiovascular system, two had been on drinking bouts, one was in severe diabetic acidosis on admission and one was uremic on admission. In two other cases the drug was prematurely stopped through error, and this seemed to play a part in the eventual outcome.

As table 4 suggests, no selection of cases was made, and sulfapyridine was not withheld because of the apparent terminal condition in any case.

SUMMARY AND CONCLUSIONS

1. An analysis of 270 cases of pneumococcal pneumonia reveals that treatment with sulfapyridine resulted in a shortened period of pyrexia, a sterilization of the blood stream and a low mortality rate.

2. Blood determinations for sulfapyridine show an irregular but prompt absorption and fail to show a correlation between the blood level and the clinical response.

3. The incidence of serious toxic reactions is low. Nausea and vomiting are frequent.

4. Whether serum should be administered also, particularly to seriously ill patients, is still *sub judice*.

5. Examination and typing of any available bacteriologic specimens—sputum, blood, spinal or pleural fluid—should not be abandoned. It gives information of value in diagnosis, in prognosis and in possible further specific therapy.

REPORT OF CASES

CASE 1 (chart 1).—D. M., a woman aged 37, was admitted to Bellevue Hospital on the sixth day of acute illness. Physical and x-ray examinations showed consolidation of the right lower

Chart 5.—Clinical course in case 5.

lobe. Type I pneumococci were recovered from the sputum and from the blood. On sulfapyridine she improved, and the blood became sterile. Through error, sulfapyridine was stopped after 16 Gm. had been given, whereupon the temperature rose and the blood culture again became positive. When administration of the drug was resumed the blood again became sterile and the patient recovered, although a low grade fever persisted for nearly three weeks.

CASE 2 (chart 2).—S. V., a woman aged 26, was admitted to the New York Hospital on the fourth day of acute illness. She gave a past history of rheumatic fever and rheumatic heart disease. On admission the sputum showed type II organisms and the blood culture showed 25 type II pneumococci per cubic centimeter. The physical and x-ray examinations revealed pneumonia involving the right middle lobe, the right lower lobe and the left lower lobe. Sulfapyridine was started shortly after admission to the hospital. On the second and third days after admission, which were the fifth and sixth days of illness, a total of 458,500 units of type II rabbit serum was administered. The toxemia subsided promptly. Blood cultures were taken daily for the first four days and were sterile. After treatment was commenced the patient made a rapid recovery. There was no nausea or vomiting and no other reaction to either the sulfapyridine or the serum.

CASE 3 (chart 3).—A. D., a woman aged 68, was admitted to Bellevue Hospital on the fourth day of a very acute illness. On admission the sputum showed type III pneumococci and the blood contained 25 type III organisms per cubic centimeter. The leukocyte count was only 5,980. Sulfapyridine was started as soon as the clinical diagnosis of pneumonia was made. Early on the second day 200,000 units of rabbit serum was injected intravenously. The toxemia was quickly controlled. Later blood cultures were sterile. The white blood cell count rose from 5,980 to 13,150 during the period in which sulfapyridine was given. Because of the grave prognosis in such a case, the drug was continued until 46 Gm. had been given. There was no gastric irritation and no other untoward reaction.

CASE 4 (chart 4).—H. C., a Negro aged 32, was admitted to Bellevue Hospital on the fourth day of his disease. The sputum showed type V organisms. Blood culture was sterile. Physical and x-ray examination revealed consolidation of the lower part of the right upper lobe. He received 16 Gm. of sulfapyridine; recovery was prompt and uneventful.

CASE 5 (chart 5).—A. S., a woman aged 28, was admitted to the New York Hospital on the third day of illness with pneumonia involving the entire left lower lobe. On admission the

Chart 4.—Clinical course in case 4.

sputum showed type XVIII pneumococci. The blood culture was sterile and the white blood cell count was 14,800. Sulfapyridine was started the day of admission and was continued for three and one-half days until 20 Gm. had been administered. There was a quick response to the drug and no reactions occurred.

140 East Fifty-Fourth Street.

ABSTRACT OF DISCUSSION

DR. RUSSELL L. CECIL, New York: In these reports on chemotherapy in pneumonia one notices the strikingly low death rate. The standard death rate from pneumonia at Bellevue Hospital runs from 35 to 40 per cent. In serum treated cases this was cut about half in two. With sulfapyridine, the death rate was reduced to 12 per cent. If the cases in which death occurs within twenty-four hours are eliminated, it is 8 per cent. In a series of seventy-five odd cases that Dr. Lawrence and I have seen in private practice, the death rate runs about 5 or 6 per cent with sulfapyridine. This is a better figure than we have ever been able to obtain with serum alone. The fact remains though that when serum is used under ideal conditions, such as those obtaining at the Rockefeller Institute, at Harlem and in certain other places, the figures are almost as good as with sulfapyridine therapy, if we make an exception of type III, in which serum has not been so striking as sulfapyridine. One of the most interesting features of this paper is the remarkable effect of sulfapyridine therapy on type III pneumonia. The death rate in our work in New York has usually run around 40 to 50 per cent, some winters even higher. In Plummer and Ensworth's series the death rate in the type III cases was only 11 per cent. In thirty-eight cases of type III pneumonia which we have treated this winter in private practice, in which we had expected a death rate ordinarily of 50 or 50-odd per cent, the death rate was only 10 per cent. Pneumonia has been milder this winter than usual, but that is because the distribution of types has been different. The good old type III pneumonia is just as severe as it has ever been. The same is true of type II pneumonia. We have had a particularly high incidence of type III and a low incidence of types I and II. Take any group of type III pneumonias this winter or any other winter and they run true to form. We have a double-barreled gun for the treatment of pneumonia, and whether we need both barrels or only one remains to be seen. Dr. Bullowa and Dr. MacLeod expressed it very well when they said that serum fortifies the pneumonia patient; sulfapyridine injures the pneumococcus. For the present we must keep our serum handy and use it in severe cases along with sulfapyridine, and we must continue to type our pneumonias in order that we may get all the better oriented with regard to this new form of therapy.

DR. H. F. FLIPPIN, Philadelphia: There is less variation from year to year in the virulence of the pneumococcus in the lower types, particularly type I infections. Since last fall my associates and I have treated over 500 adult pneumonia patients with sulfapyridine. Of this number 101 represent type I. Twenty-one of these had positive blood cultures with a mortality rate of 14.3 per cent. The mortality rate for the entire type I series was 5.8 per cent. During this same time eighty-eight patients of type I were treated with various forms of therapy at the Philadelphia General Hospital. In those receiving nonspecific, serum and sulfapyridine treatments the mortality rates were 44.4 per cent, 11.5 per cent and 3.7 per cent respectively. We have found it advisable to give rather large total doses to those with blood stream infections. In such cases a total of 25 Gm. and usually more has proved necessary, as it is important to continue the drug despite a normal temperature. Some significance can be placed on the white blood count following the administration of sulfapyridine. In most instances the critical drop in temperature is closely followed by a marked reduction in the total white blood count, but if it remains elevated it is wise to look for a spread in the infection or for complications. Our experiences correspond to those of Drs. Plummer and Ensworth concerning the toxic manifestations of sulfapyridine. The gastrointestinal symptoms of nausea and vomiting have proved the most troublesome.

To combat these we have used with varying success such adjuvants as intravenous chlorides, chloral hydrate, barbiturates and, more recently, nicotinic acid. Microscopic hematuria has been detected in approximately 5 per cent and gross hematuria in 1 per cent of our patients. Careful pathologic studies in the fatal cases have failed to show any evidence of renal damage attributable to the drug. This question of possible renal involvement is one that remains to be properly evaluated. We have not had enough occasions to use both serum and sulfapyridine in the same case to express an opinion as to the merits of combined therapy. At this time we feel that sulfapyridine is an effective drug in the treatment of pneumococcal pneumonia and, if used with regard to its toxic effects, it is a therapeutic agent with a satisfactory margin of safety.

DR. F. JANNEY SMITH, Detroit: In the preceding eight years at the Henry Ford Hospital, 678 adults suffering from lobar pneumonia were treated by all methods. There were 253 deaths, giving a mortality rate of 37 per cent. In the past winter seventy unselected, consecutive adult patients were treated with sulfapyridine. There were six deaths, or a mortality of 8.5 per cent. Two of the patients died after being in the hospital fourteen hours or less. If those could be subtracted, the mortality rate would be 5.5 per cent. The average amount of the drug administered was from 15 to 25 Gm. Failure of prompt defervescence in three cases led to the justifiable suspicion that another organism than the pneumococcus was responsible. Autopsy showed that in two of these instances the staphylococcus was responsible and in one the tubercle bacillus. Nausea was the common toxic manifestation. No serious effect was shown on the blood picture. Illustrating renal toxicity, one patient, a white woman aged 54 with type III pneumonia, whose treatment was begun on the eighth day, showed a 3+ albuminuria and few red cells before the beginning of the drug treatment. After 8 Gm. of the drug, anuria developed. Renal function was reestablished in two days, but a new consolidation developed on the contralateral side and death occurred without further specific treatment. Autopsy and microscopic studies showed acute toxic nephritis with tubular degeneration and focal necrosis, the picture being similar to that seen in some of the metallic poisons, particularly mercury, except that it was focal instead of diffuse. There was also present focal necrosis in the adrenals. Another patient, a white man aged 64 with type IV pneumococci in the sputum and blood, had an excellent response to the drug but died after eighteen hours of normal temperature of a ventricular tachycardia. It is impossible to state whether this complication was due to his disease or whether it was related in any way to the drug therapy.

DR. L. D. THOMPSON, St. Louis: I have observed this winter two series of cases, one treated with type specific serum and one with the drug. The series are not comparable because the serum treated patients were picked. They consisted of types I, II, V, VII, VIII and XIV but no type III patients, whereas the drug treated patients included a large number of youngsters, that is below 2 years of age, and also a large number of type III patients. However, I think that some of the figures are significant. Of the 121 type specific treated patients five died, a mortality rate of 4.13 per cent. When you consider some of the circumstances of those deaths, it is even more striking. Of the five deaths, two were in type I, one patient seen first on the fourteenth day and one seen first on the fifth day. One had type II pneumonia, seen for the first time on the eighth day. Two had type V, one seen on the sixth day and one on the twenty-first day. I can make the statement that in this series no patient seen before the fifth day was lost. Another striking feature was that in the serum treated cases we had an appreciable incidence of type VII and type VIII pneumonia with no deaths at all, although the bacteremia in type VII was 15.3 per cent and in type VIII was 5.2 per cent. In the drug treated cases, 145, we had a gross mortality of 10.3 per cent. Twenty-five odd cases of those were type III, with a mortality rate of 16 and a fraction per cent. In type VII cases, drug treated, we lost one out of four and in type VIII, drug treated cases, we lost one out of six. Neither of these deaths occurred in a case of bacteremia. In this small series the drug appeared to be definitely less

efficient for types VII and VIII than did the type specific serum. Another point of difference with the drug treated series is that three patients seen before the fifth day died, one type III, one type XVIII and one we were unable to type.

DR. JESSE G. M. BULLOWA, New York: How can we select patients who require serum as well as sulfapyridine? Drs. Bukantz, deGara and I studied the concentration of polysaccharide in the blood of twenty-five patients. Twenty-one had either small amounts or no polysaccharide. These patients all recovered after treatment with sulfapyridine, with serum and with the combination. The four patients who had large amounts of polysaccharide in the blood died. A patient with pneumococcus type VII pneumonia was seen on the third day of the illness and was refractory to serum given in large amount. The elevated temperature continued and on the ninth day, when the blood was heavily invaded, he was given serum and sulfapyridine. He was very much improved. When the sulfapyridine was stopped after a period of eight days, the patient again became ill, and on the thirty-second day of the illness he was again given sulfapyridine, with the result that the temperature and the pulse fell. During this time the patient made his own antibodies. The fall in concentration of capsular polysaccharide was coincident with clinical improvement. Then treatment was withheld for a while. He had a persistent atelectasis, which on bronchoscopy showed granulation tissue in the bronchus. The atelectasis cleared, but the blood of the patient, who was apparently getting well, was reinvested. This time meningitis developed. The patient's organisms had apparently become fast to the sulfapyridine, and ultimately, having developed a bacterial endocarditis, he died. It is possible that pneumococci of types II and V, which are related, may be more resistant to the action of sulfapyridine than some other pneumococci. A patient 29 years of age, with a pneumococcus type II pneumonia, was treated on the third day, receiving an initial dose of 5 Gm. of sulfapyridine and 1 Gm. every four hours thereafter. Though we obtained a concentration of 7.5 mg. of free sulfapyridine per hundred cubic centimeters, the patient died on the fourth day with a rising temperature. The requirement of an adequate concentration of sulfapyridine is illustrated by a patient who had a double infection, in whom pneumococcus type IX was found in the sputum and pneumococcus type V in the blood on the third day. There were then only six colonies. He received 240,000 units of pneumococcus type IX rabbit serum; his temperature and pulse fell on the fifth day and there were antibodies for pneumococcus type IX. We did not obtain a very high concentration of sulfapyridine in spite of the unusually high dosage. On the fourth day he had 1.7 mg. per hundred cubic centimeters of blood. Apparently the sulfapyridine had no effect on the bacteremia due to pneumococcus type V; it had increased on the fifth day to 123 colonies. He died on the sixth day.

DR. W. D. SUTLIFF, New York: Drs. Plummer and Ensworth and other workers with hospital facilities are laying a firm foundation for the use of sulfapyridine in general practice. They are showing not only that sulfapyridine is an effective therapeutic agent but that it must be used with certain precautions. During the same period as that during which the authors' figures were collected, the pneumonia control division of the New York City Department of Health assembled similar figures from a large number of physicians for patients treated at home as well as in the hospital. During January, February and March 1939 a total of 1,354 reports were returned by physicians who received serum from the department of health. Pneumonia cases caused by eight different pneumococcus types were treated with serum. The fatality rate varied from 4.5 per cent for 396 serum treated type I cases to 13.7 per cent in ninety-five type II cases. Fatality rates for other types ranged between these two extremes, with the exception of type XIV, which showed the very low fatality rate of 2.4 per cent in eighty-five cases, owing in part to the fact that this type was found in children and infants in about 50 per cent of the cases. Chemotherapy was employed by the general practitioner for only 228 patients. It was apparently employed for patients who were more seriously ill, as the fatality rate of 228 patients who had both serum and chemotherapy was 17 per cent. The gross fatality rate for all patients treated with serum or treated with chemotherapy in addition to serum was 8.8 per cent. All cases of certain pneumococcus types were treated with rabbit serum, and all cases of

other pneumococcus types were treated with horse serum and the results were equally satisfactory. Since April 15, when sulfapyridine was released for general sale, 126 patients treated with sulfapyridine alone have been reported to the New York City Department of Health, Pneumonia Control Division. This group of cases shows a fatality rate of 5.6 per cent, which approximates closely to that reported by Drs. Plummer and Ensworth and other observers in hospital practice. These cases all had bacteriologic diagnosis performed in the New York City Department of Health, Pneumonia Control Division stations.

DR. HERBERT K. ENSWORTH, New York: The question of picking cases for treatment with sulfapyridine or with serum or the combination is something which will have to be worked out. Fleming recently published in the *Lancet* a bacteriologic means of doing so which takes twenty-four hours. He determines whether the particular strain of the inciting organism is susceptible to sulfapyridine or not. That is an interesting way of doing it; if the process can be shortened so that we can get treatment started without undue delay it may be very valuable. Dr. Bullowa's demonstration of the significance of the polysaccharides in the urine is interesting also and it may be that from this will develop another useful aid in selecting the method of therapy most suitable for the individual patient. The present day results with serum, as Dr. Sutliff showed, are excellent. I think it shows one thing about serum, that serum is getting better; it is becoming more refined, more concentrated and more effective. All the reports of serum in recent times have shown results superior to those obtained with the serum of the older days. This also applies to type III serum, formerly thought to be of little value. We and others have seen type III pneumonia cases in which definite improvement which appeared to be due to serum has occurred. At the present time, however, sulfapyridine appears to be lowering the mortality rate in all types even more than serum does.

THE ETIOLOGIC DIAGNOSIS OF PNEUMONIA IN CHILDREN BY RAPID TYPING OF NASAL CULTURES

FRANKLIN D. POOLE, M.D.

AND
MILDRED D. FOUSEK

NEW HAVEN, CONN.

Advances in the treatment of pneumonia both with serum and with drugs have increased the importance of the etiologic diagnosis. In children, attempts to circumvent delay due to lack of sputum by obtaining tracheal specimens have been made by Bullowa¹ and by Krahulik, Rudomanski and Cunningham.²

Beebe,³ Kneeland⁴ and Webster and Hughes⁵ reported that in respiratory infections in children the respiratory pathogens, e. g. pneumococcus, influenza bacillus and hemolytic streptococcus, appear in cultures from the nasal passages. In the middle fossae of the nose in cases of lobar pneumonia, Felty and Heatley⁶ described the presence of pneumococci which corresponded to the type found in the sputum. Baker⁷ found that in early pneumonia in children the highly parasitic pneumococcus type I could be quickly

From the Children's Center of the New Haven Orphan Asylum and the Department of Pediatrics of the Yale University School of Medicine. Aided by grants from the Fluid Research Fund of the Yale University School of Medicine.

recovered from nasal swabs through mouse inoculation. These observations led us to explore the possibility of rapid typing of pneumonia in children using the quellung reaction on pneumococci which might appear in blood broth inoculated with a nasal swab.

Fig. 1.—Simplicity of normal flora.

METHOD OF STUDY

The basic medium was a fresh beef heart infusion broth with 2 per cent defibrinated rabbit's blood, 1 cc. volumes being used in ordinary test tubes and kept on the desk. The beef hearts were infused within twenty-four hours of slaughtering. The small volume and storage at room temperature were used to shorten the period of incubation. The nasal swab consisted of the ordinary wooden applicator tipped with cotton. The culture of the nose was taken by passing the swabs far back into the nasopharynx. Sometimes this was possible in only one nostril. One swab was left in the tube of blood broth and incubated at 37.5 C. Another swab taken at the same time was used to streak a blood agar plate made up of fresh beef heart blood agar with 5 per cent defibrinated rabbit's blood. The second swab was then placed in a tube of plain broth; after shaking, 1 cc. of the fluid was inoculated into a white mouse.

The clinical material consisted of patients suspected of having pneumonia admitted to the pediatric service of the New Haven Hospital. Of these, thirty-two proved to have lobar pneumonia, eight bronchopneumonia, one capillary bronchitis, two bronchitis and five acute upper respiratory infections and questionable pneumonias.

RESULTS

Figures 1 and 2 are reproductions of photographs of nasal cultures on blood agar plates in a normal child and in lobar pneumonia respectively. Figure 1 (normal) shows the simplicity of the normal flora, which consists merely of diphtheroids and staphylococci.

Figure 2 (lobar pneumonia) shows the predominance of pneumococci that in cases of pneumonia one can get the pneumococci in almost pure culture from the nose and that only a small volume of medium is required constitute the basis of the success of the method.

Thirty-four cases of pneumonia and severe respiratory infections were typed by the rapid method. The

time required in typing ranged from one and three-quarters hours to six hours. In the average case from three to four hours' incubation of the 1 cc. volumes of blood broth inoculated in the manner described was all that was necessary to obtain a culture suitable for a typing of the pneumococci. On the other hand, when a 5 cc. volume of blood broth was used, from twelve to eighteen hours was found to be the time necessary for incubation before the quellung reaction could be employed successfully.

The accompanying table, summarizing the cases of lobar pneumonia, bronchopneumonia and upper respiratory infections examined, shows the organisms obtained from the nose and throat, from white mouse inoculation, from blood culture and from exudates from the ear and pleural cavity.

RESULTS

The table shows a contrast between the predominance of the parasitic pneumococcus in the nasal cultures on the one hand and the variety of organisms of the throat on the other hand. Pneumococci were recovered from the nasal cultures in twenty-nine of the thirty-two cases of lobar pneumonia. In six instances a check on the method of the typing by nasal cultures was possible by means of a comparison of types found in blood cultures, pus from the ear, pleural cavity and nose; the nasal method was upheld six times (cases 1, 7, 10, 11, 14 and 18). The nasal method failed in three cases (cases 6, 23 and 32). The unsuccessful examination for pneumococci in the nose, as in cases 6, 23 and 32, was made on the first and second days of disease and could not therefore be ascribed to a late examination, as might have been expected from Baker's work.

Fig. 2.—Predominance of pneumococci in nasal culture from a child with lobar pneumonia.

The three cases in which the method failed were typical of lobar pneumonia in respect to onset, physical signs and roentgenographic evidence.

Several types of pneumococci were recovered from the nose, the throat or other sources in seven cases of lobar pneumonia (cases 4, 5, 17, 21, 27, 29 and 31) and in one case of bronchopneumonia (case 34). In the three instances (cases 4, 5 and 17) in which the distinction could be made, a highly parasitic pneumococcus was found in the nasal culture.

* Predominant organism.

The first day of disease in the pneumonias was calculated as the first day of high fever, cough, vomiting or convulsion.

In five cases of bronchopneumonia the pneumococcus was not found in the throat culture (cases 34, 37, 38, 39 and 40) but was present in the nasal cultures in all but one (case 40). Pneumococci were absent in the throat cultures in seven cases of bronchitis, upper respiratory infections and questionable pneumonias (cases 41, 42, 44, 45, 46, 47 and 48), whereas they were present in every case in the nasal culture. In one case of bronchopneumonia the pneumococcus was not recovered from either the nose or the throat culture, but an unclassified type was obtained from mouse inoculation but not from aural exudate, which contained a hemolytic streptococcus (case 40).

SUMMARY

The method of rapid typing of nasal cultures has some limitations but is of value in the etiologic diagnosis of pneumonia. The method is of special value in pediatrics but, judging from Felty and Heatley,⁶ it may be valuable also among adults. Even with the advent of chemotherapy in pneumonia the method still is of importance, because it is desirable to know whether or not the inciting agent is a pneumococcus or a hemolytic streptococcus. If the etiology is pneumococci it is important to recognize the high parasitic strains which usually occur in lobar pneumonia and to recognize those strains which are more common in bronchopneumonia or the so-called "atypical" or viral pneumonias.

THE SULFAPYRIDINE TREATMENT OF
PNEUMONIA IN CHILDREN

CHARLES HENDEE SMITH, M.D.

AND

ROSA LEE NEMIR, M.D.

NEW YORK

There have been a number of reports concerning the use of sulfapyridine in the treatment of pneumonia in infancy and childhood during the past few months.¹ A review of the literature will not be made here. The present series of ninety-three cases is reported because of the successful results in lobar (pneumococcus) pneumonia from the use of the drug in small doses and for a short time.

These patients were treated with sulfapyridine in the Children's Medical Service of Bellevue Hospital between January and July 1939. All patients under 12 years of age having pneumonia had a bacteriologic study with cultures from the throat by the technic described² for pneumococcus typing and blood agar plates for streptococcus study in many cases (table 1). No attempt was made to have a control series, since the early results made it seem unfair to withhold the drug from sick children. Our experience with many hundreds of cases during the past years is a reasonable index of the expected course and outcome of pneumonia

in childhood. All patients had roentgenograms taken during the pneumonia with anteroposterior and lateral views, often repeated.

The diagnosis of the clinical forms of pneumonia was made on the basis of criteria previously outlined.³ The varieties studied during this period are noted in table 2. The majority of the patients had lobar pneumonia (seventy-nine of the ninety-three), distributed from 2 months to 13 years of age. There were twenty-nine patients under 2 years with lobar pneumonia and fifty over 2 years (table 1). All of the eleven patients with bronchopneumonia were under 2 years of age.

Sulfapyridine was given by mouth, in most cases crushed and mixed with cereal, apple sauce or fruit juice. It was usually given shortly after a meal to minimize the possibility of nausea or vomiting. In the early cases 0.2 Gm. per kilogram of body weight (1½ grains per pound) was given on the first day, and half this amount on the subsequent days. We soon found that equally prompt defervescence was observed with three fourths of this dosage in children over 2 years. The infants, however, seemed to require the original dosage, and this was continued for them. No child received more than 4.5 Gm. a day, and the average total amount given to a child was 5.48 Gm. The average total dosage for an infant under 2 years was 3.99 Gm.

Half of the patients were treated for only two days and 75 per cent for not more than three days. The average duration of treatment was 2.6 days. It is our experience that if sulfapyridine affects the course of the pneumonia it does so within eighteen to thirty-six hours. In the first few cases treated it was given for from five to six days after the crisis, but the prompt fall of temperature after the drug is begun led us to shorten the time of administration. In the larger part of this series the drug was continued for only eighteen to twenty-four hours after the crisis. No definite recurrences of pneumonia have been noted. Five patients had subsequent short rises of temperature, probably not true relapses of pneumonia.

Blood sulfapyridine determinations were done on many but not on all patients. The concentration was found to vary widely with the same dosage of drug, from less than 1 mg. to 12 mg. per hundred cubic centimeters. Three patients whose concentration was 0.8 mg. per hundred cubic centimeters had a crisis completed within eighteen hours after the drug was given. The average blood sulfapyridine determination was from 2 to 4 mg. per hundred cubic centimeters, and with this level in most cases prompt crisis was noted.

UNFAVORABLE REACTIONS

The most frequent reaction was vomiting, usually of only one or two doses, occurring in 15 per cent of the patients. This symptom was never severe enough to require stopping the drug. Vomiting can be greatly reduced by giving the sulfapyridine with food or directly after meals, a precaution which is often neglected in hospital practice. None of the patients became cyanotic from the drug, although several were cyanotic when it was first given. Extreme restlessness and delirium were observed in four patients, one of whom had a blood sulfapyridine concentration of 12 mg. per hundred cubic centimeters, the highest in our series. This baby had a peculiar agitated expression and constantly threw himself about. His extreme restlessness required the use of

restraints to prevent falling out of bed. This agitated restlessness is not a part of any pneumonia picture. All four of these patients presented an alarming state; they had a peculiar intense pallor, although they were not anemic. They were improved by sedatives (phenobarbital), by a large amount of fluids and by discontinuing the drug for one or two doses. Two of these

babies were placed in oxygen tents without improvement of the nervous symptoms. A transient mild hematuria was observed in one patient. This child had received only 0.12 Gm. per kilogram of sulfapyridine; hematuria appeared on the third day of treatment and cleared within a few days. It must be pointed out that hematuria occasionally occurs in pneumonia without the use of sulfapyridine. No other toxic symptoms were observed.

RESULTS

The prompt and consistent precipitation of crisis following the oral administration of sulfapyridine has been reported by many observers, and our experience is no different. This reaction occurred within eighteen to twenty-four hours in sixty-nine of the seventy-nine patients with lobar pneumonia. Of course, it is possible that the drop in temperature of some of the patients coincided with the normal crisis, but such an explanation cannot account for all the reactions, particularly in those treated very early in the disease. Many of the patients treated on the eighth to the eleventh day were acutely ill with type XIV pneumonia, in which the average duration is from eight to fourteen days.⁴

It has been stated that, although sulfapyridine provokes a crisis, the disease runs its course, and the consolidation does not resolve sooner than it would have done if untreated. This suggestion is contrary to our experience. The x-ray shadows and the physical signs begin to clear at once just as they do after a normal crisis.

4. Nemir, Rosa Lee: The Significance of Pneumococcus Typing in the Pneumonias of Childhood, read before the Section on Pediatrics, American Medical Association, St. Louis, May 18, 1939, to be published.

The three patients with lobar pneumonia who failed to show the typical response to sulfapyridine were all infants under 2 years of age, all severely ill. It is possible that the sustained temperature, in the first one of these patients was a febrile evidence of sulfapyridine intolerance or intoxication, since this baby had other signs of reaction, namely extreme restlessness, delirium, pallor and marked anorexia. His blood sulfapyridine determination was 12 mg. per hundred cubic centimeters. The second patient is remarkable only because he required forty-eight hours' therapy to produce a crisis. The third baby had pneumonia three times previously at Bellevue Hospital, some of these atypical pneumonia. We cannot explain his unusual reaction to sulfapyridine.

In five cases of lobar pneumonia, although the usual reaction occurred after sulfapyridine, secondary short febrile rises occurred. It has been suggested that the bacteriostatic action of sulfapyridine may produce improvement for a short time and then be followed by a relapse. There were only five patients whose temperature charts might be so interpreted. Only one of these cases clinically appeared like a pneumonia during the second temperature rise which yielded promptly to renewed treatment. The dosage of sulfapyridine was probably inadequate in case 5, but readministration of the drug was followed by prompt crisis. The other three patients had no new signs of pneumonia. One of these received no more drug, and the fever subsided just as promptly as in the cases in which it was given, so that it is not certain that any patients had true relapses. Short febrile episodes are often seen in hospital patients from insignificant causes. These three patients may all have had transient fever not associated with pneumonia. Roentgenograms in all five cases showed clearing pneumonias and no new consolidation. It is noteworthy that four of the five patients had pneumococcus type XIV pneumonia, a disease known for its severity. It is suggested also that type XIV pneumonia may require a somewhat greater dosage than the other pneumococcic pneumonias.

‡ Type of pneumonia described by Lincoln, E. M.; Smith, C. M., and Kirmse, T. W.: Subacute Pneumonia in Children, J. Pediat., to be published.

In eleven cases of true bronchopneumonia we have failed to observe the same dramatic, prompt response to sulfapyridine seen in cases of lobar pneumonia. The temperature of the patients with bronchopneumonia remained elevated, and they seemed only slightly improved. Our series of this form of pneumonia this year is small, however. Four of the eleven patients died, approximately the average mortality rate for bronchopneumonia during the past eight years. A much longer time will be needed to evaluate sulfapyridine therapy in this form of pneumonia. Kohn⁵ reports no

5. Kohn, Jerome, et al.: Sulfapyridine Treatment in Infants and Children, Including Treatment of Pneumonia During Pertussis, read before American Academy of Pediatrics, Region 1, New York, in June 1939; abstr., J. Pediat. 15: 449 (Sept.) 1939.

effect on bronchopneumonia in his experience at the Willard Parker Hospital.

One patient clinically thought to have bronchopneumonia died and at autopsy was found to have lobular pneumonia, probably from aspiration. The walls of the bronchi were normal. This 6½ months old baby was admitted to the hospital for a diarrhea from which he was recovering when he developed pneumonia. Type XIX pneumococcus was found. The baby was treated promptly with sulfapyridine but died within thirty-six hours after the onset of the pneumonia.

There was one death among the seventy-nine patients with lobar pneumonia. This severely ill 16 months old baby died suddenly on the third day after admission to

TOTAL WITH CRISIS IN 1 DAY 69

Typical response of sixty-nine cases of lobar pneumonia in which there was a crisis within twenty-four hours after sulfapyridine was started. At the right is shown the number of days the drug was given in each case. Note the short duration of its administration in all except a few (early) cases.

the hospital. A roentgenogram taken the day before death showed a pyopneumothorax (not diagnosed clinically), which was probably responsible for the death. No autopsy was obtained.

Only one patient developed empyema, an infant with type I lobar pneumonia. He developed physical signs, and a roentgenogram indicated suppurative pleurisy. On pleural tap 2 cc. of thick pus was removed, from which type I pneumococcus was cultured. No further pus was ever found and the patient promptly recovered. This abortive course of empyema has been rarely encountered in our many years of observation of empyema, especially that following type I pneumonia.

Pneumococcic bacteremia was found in only one patient, a boy of 8 years, with type I lobar pneumonia. His defervescence occurred within eighteen hours in the typical manner. The drug was cut after thirty-six hours, and the report of the blood stream invasion was obtained after the drug had been discontinued. Even with this small amount of therapy, the blood stream was sterile. As a precaution the drug was readministered for twenty-four hours, but all further blood cultures were sterile. Streptococcus viridans was found in two blood cultures from a patient with bronchopneumonia. The blood cultures were sterile after several days' treatment with sulfapyridine, and the patient recovered.

COMMENT

The consistent prompt crises observed in our patients with lobar pneumonia following the oral use of sulfapyridine is convincing to us that the drug is very efficacious in treating pneumococcic pneumonia (and perhaps also that due to the streptococcus). But the value of a therapeutic agent in pneumonia cannot be established in one season's time, since pneumococci are known to vary in their distribution and virulence from year to year. It may be that results will be less good in more serious epidemics.

In the present season we have had a lower percentage of type I pneumonia (10.9 per cent for the present year as compared to 17.8 per cent average for the past six years). There were probably more mild cases this season than usual, although many patients were very severely ill.

The failure of bronchopneumonia to respond favorably to sulfapyridine may be explained on the basis of etiology, since the bacteriology is variable and often no pneumococci are found. If a filtrable virus is the etiologic agent of bronchopneumonia, as has been suggested by various workers and by some experimental work with animals,⁶ the explanation for the different reactions of these patients to the drug is probably indicated. Sulfapyridine has not been especially useful for diseases due to filtrable viruses.

For the older child sulfapyridine may well be the answer to the treatment of lobar pneumonia in the great majority of cases. In this age group (2 to 13 years) pneumonia is a milder disease with a much lower incidence of bacteremia and deaths than in adults. Even though the death rate in children may not be greatly affected, since it is already low, the shortening of the disease and the avoidance of complications justify the use of the drug. There may always be some patients who will require specific antipneumococcus serum therapy as well as the bacteriostatic agent sulfapyridine. Infants who are debilitated, chronically ill or anemic and who may be unable to produce their own immune bodies may need specific serum as well as sulfapyridine. The necessity for obtaining a pneumococcus typing, preferably before chemotherapy is given, is clear. If sulfapyridine is not effective in the usual time, from eighteen to twenty-four hours, specific serum may be given without delay if typing has already been done. In comparing results from different clinics with sulfapyridine in pneumonia, it is important to compare the results with reference to the types of pneumococci. It is known that the duration, severity and fatality of pneumonia is directly associated with the pneumococcus types.

We wish to reiterate that it is not necessary to continue sulfapyridine for many days in the fear of a relapse. In this series the drug was given only 2.6 days on an average. If the few early cases are excluded, this time drops to 2.3 days. The average total amount was 3.99 Gm. for infants under 2 years and 5.48 Gm. for patients 2 years of age and over. The largest amount given to any patient was 13.25 Gm. The advice to "try to stop the drug after 300-450 grains (20-30 Gm.) have been given"⁷ seems unwise in suggesting that these large amounts are usually needed. Sulfapyridine may be a poisonous drug in some cases, as is indicated by the reports of cyanosis, hematuria, leuko-

7. Report of the Committee on Immunization and Therapeutic Procedures. American Academy of Pediatrics, June 1939, p. 13.

penia, delirium, liver damage and even death associated with the use of the drug. We believe that sulfapyridine should be given no longer than is necessary to effect a crisis and should be stopped very soon thereafter. To continue medication longer is unfair to the patient, just as it is with any drug having a cumulative poisonous action. The fact that we have observed no true relapses and have had no toxic symptoms of importance indicates the value of a wider trial of the small dose and short administration. Others⁶ have produced a crisis by one day's treatment and even by a single large dose.

RESULTS

1. From January to July 1939, ninety-three patients were treated with sulfapyridine; seventy-nine with lobar pneumonia, eleven with bronchopneumonia, one with lobular pneumonia and two whose pneumonia was classified as "subacute pneumonia."

2. In bronchopneumonia there was no apparent effect on the course in any of the eleven patients, four of whom did not survive.

3. In uncomplicated lobar pneumonia with small dosage, for two or three days only, a crisis occurred within eighteen to twenty-four hours in seventy-four of the seventy-nine cases. In the five other cases crisis occurred in forty-eight hours. One death occurred from pyopneumothorax. The short duration of therapy is emphasized not only because of its success but also because of the very few untoward reactions observed.

CONGENITAL LESIONS OF THE NECK

CONRAD J. BAUMGARTNER, M.D.

LOS ANGELES

The neck with its complex embryologic evolution is particularly subject to developmental anomalies. Among these may be mentioned branchial cysts and fistulas, cystic hygromas, submaxillary and submental inclusion cysts, dermoids, an accessory auditory canal, a lingual thyroid and an aberrant thyroid.

Fig. 1.—Schematic drawing showing development of branchial apparatus. I. M., mandibular arch; II. H., hyoid arch; III, IV, V, third, fourth and fifth branchial arches; 1 B. P., 2 B. P., 3 B. P., first, second and third branchial pouches; 1 B. G. R., 2 B. G. R., 3 B. G. R., 4 B. G. R., first, second, third and fourth branchial grooves.

Successful surgical assault of any congenital lesion consists of a complete reversal of the embryonic processes causing the condition in question. Obviously, in the subject being discussed at least a working knowl-

edge of the embryologic anatomy of the neck is essential. The frequency of recurrences noted following surgical attack is evident testimony to the fact that a fundamental knowledge of the subject is not generally held. In the short space allotted, therefore, I shall sketch diagram-

Fig. 2.—Appearance of branchial fistula tract which has been injected with iodized oil. Note direction corresponding to the sternomastoid muscle and medial arching of the tract at the level of the middle portion of the posterior belly of the digastric muscle.

atically a rough working model of some of the embryology of the neck and its relationship to some of the common anomalies.

EMBRYOLOGY

Although noteworthy studies of the branchial apparatus have been made by His, Rathke, Born and others, undoubtedly the greatest single contribution is that of Wenglowski,¹ who in 1912 published a monograph giving the results of a detailed study of serial sections of a large number of human embryos from 2 to 49 mm. in length. The clinical applications of these results were shown by Herbert Willy Meyer² in a series of studies published in 1932.

During the second week of embryonic life certain changes take place in the fetal foregut (fig. 1). From the interior lateral walls five outpouchings occur. These are the branchial pouches. Simultaneously the external ectoderm becomes indented over the corresponding pharyngeal pouches. These are the branchial grooves. The pouches and grooves approach each other so that entoderm and ectoderm come into contact, the contracting area being the closing membranes, which in gill bearing animals disappear, forming the gill clefts, which open from the pharynx to the exterior. The mesoderm is thus pushed aside into six rounded bars, the branchial arches, of which the first two partially telescope over the remainder, forming the cervical sinus. Each arch

2. Meyer, H. W.: Congenital Cysts and Fistulae of the Neck, Ann. Surg. 95: 226-248 (Feb.) 1932; footnote 3.

contains a cartilaginous bar and in each is also the anlage of one of the primitive aortic arches.

The first or mandibular arch gives origin to the muscles of mastication, lower lip, mandible and anterior part of the tongue, while the cartilaginous bar forms portions of the middle ear and mandible. From the second or hyoid arch are developed the structures of the upper part of the neck and from its cartilage the styloid process, the styloid ligament, the lesser cornu of the hyoid and, with assistance of the third arch, the body of the hyoid and posterior part of the tongue.

The remaining arches all give origin to structures in the vicinity of the hyoid, the sixth giving origin to the cricoid, arytenoid and tracheal cartilages.

As to the branchial grooves, no traces persist of any with the exception of the first, which gives origin to portions of the auricle and external acoustic meatus and with it the possible, although rare, congenital anomaly of the accessory ear.

Proceeding to the interior, one notes that from the first branchial pouch are formed the auditory tube and the tympanic cavity, the tympanic membrane arising directly from the first closing membrane. In the second pouch lies the angle of the tonsil; but of particular significance is the third pouch.

BRANCHIAL CYSTS AND FISTULAS

Wenglowski¹ demonstrated that from the third pouch on either side two tubules descend into the mediastinum to form the thymus. The course of these

Fig. 3.—Excision of branchial fistula, showing armamentarium and method of massaging methylene blue into the tract. (By courtesy of Surgery, Gynecology and Obstetrics.)

tubules is in the general direction of the sternomastoid muscles, laterally to the thyroid and anterior to the carotid sheath. Furthermore, Wenglowski was able to demonstrate remnants of this tubule in adult necropsy dissection.

There are several theories regarding the evolution of branchial cysts and fistulas: 1. That they are caused

by vestigial remains of the branchial grooves or pouches. 2. That they are a result of an embryonic perforation of the closing membrane. 3. That they are a persistence of the cervical sinus formed by a telescoping of the rapidly growing first and second arches over the remain-

Fig. 4.—Branchial fistula. The tract lies along and beneath the sternomastoid muscle and extends up to the midportion of the posterior belly of the digastric, where it arches medially to enter the tonsillar fossa.

ing arches. 4. That they are due to remains of the thymic duct, which descends from the third pharyngeal pouch, as demonstrated by Wenglowski in 1912.

Now as one compares the anatomic direction of the descent of the thymic duct with that of so-called branchial cysts and fistulas, one finds a rather exact corollary. Clinically these manifest themselves as a fistula or cyst containing a mucoid or milky material, having a uniformly characteristic position along the anterior border of the sternomastoid, extending under it but lying anterior to the carotid sheath. Although occurring at any level of the neck, the tract invariably runs upward beneath the anterior portion of the sternomastoid muscle to the posterior belly of the digastric, where it arches medially behind the stylopharyngeus muscle to end in the tonsillar fossa. The course can at times be demonstrated by x-ray examination preceded by iodized oil injection of the tract (fig. 2). The tract is lined with ciliated epithelium and layers of squamous epithelium surrounded by stroma infiltrated with round cells. As Herbert Willy Meyer has pointed out in his studies in 1932³ and again in 1937,⁴ these have nothing whatever to do with any branchial cleft affairs and should therefore be considered as thymic duct cysts and fistulas. Complete removal to the pharynx is of course necessary. I prefer to inject the tract with methylene blue (fig. 3) and follow this with a saline irrigation to remove the excess stain. This prevents discoloration of the surrounding territory during the dissection to

follow (fig. 4). On completion of the dissection, the stump should be inverted into the pharynx when this is possible (fig. 5).

True branchiogenic fistulas do occur, but they are indeed rare and must occur within the realm of the

branchial apparatus, which at best is not much lower than the hyoid, and the tract, instead of being lined with squamous epithelium, is lined with vestiges of skin, hair follicles, sweat glands and sebaceous glands.

Fig. 6.—Excision of thyroglossal duct fistula. The platysma muscle has been reflected and dissection carried to the hyoid bone. (By courtesy of Surgery, Gynecology and Obstetrics.)

ABERRANT THYROID

Proceeding with the embryologic study, Wenglowski found that from the fourth pouch not only the parathyroids developed but that a comparatively short tubule passed on either side in a somewhat medial

direction to form the lateral lobes of the thyroid. Now it is not universally agreed that the thyroid has more than one anlage, but the distribution of aberrant thyroids can certainly be explained on this basis.

LINGUAL THYROID AND THYROGLOSSAL DUCT CYSTS AND FISTULAS

During the third week two rounded buds appear on the ventral side of the first two arches. The anterior bud, the tuberculum impar, forms the anterior part, and the posterior bud, the copula, forms the posterior part of the tongue. From a depression—the foramen caecum—between the two buds a tubule descends to and around the hyoid bone and proceeds downward to be the anlage of the thyroid. This tubule is the thyroglossal duct. Any arrest above the hyoid in its descent will result in the anomalous lingual thyroid, which

Fig. 7.—Excision of thyroglossal duct fistula. The midportion of the hyoid bone is being removed with bone forceps, according to the method of Sistrunk. (By courtesy of Surgery, Gynecology and Obstetrics.)

Catell and Hoover⁵ reported as occurring only twice in 7,600 thyroids operated on at the Lahey Clinic. Normally the duct atrophies, but when it remains patent in any portion a thyroglossal duct cyst or a fistula is the result.

The clinical picture is that of a cyst or fistula, which occurs near the middle of the neck, usually just below the hyoid, and moves up on swallowing. With the fistulous opening there is either a continuous or an intermittent discharge of mucoid material. Troublesome symptoms such as a choking sensation and difficulty in swallowing are rare, but secondary infection is fairly common. All too frequently the cyst is mistaken for an abscess, and consequently a history of repeated incision and drainage without cure is often noted. Adequate surgical approach was first described

5. Catell, R. B., and Hoover, W. B.: Lingual Thyroid Gland: Report of Case and Discussion of Aberrant Thyroid Tissue. *S. Clin. North America* 9: 1355-1362 (Dec.) 1929.

by Sistrunk.⁶ It consists of a horizontal incision surrounding the fistula or cyst (fig. 6). A central segment of the hyoid is then removed (fig. 7) and, since identity of the duct is usually lost between it and the foramen caecum, a portion of the tongue tissue is cored out between these two points (fig. 8).

SUBMAXILLARY AND SUBMENTAL INCLUSION CYSTS

The submaxillary and submental glands are formed in the alveolar lingual groove directly behind the first arch. They begin as small furrows, the posterior parts of which close over to give rise to a number of buds forming lobules of the gland. Any obliteration of these tubules will produce inclusion cysts, in which case surgical assault consists in removal of the offending gland itself.

CYSTIC HYGROMA

In a recent review⁷ of congenital lesions of the neck I reported eleven thyroglossal duct cysts and fistulas and four so-called branchial cysts and fistulas. We had at that time four cases of cystic hygroma. After a

Fig. 8.—Excision of thyroglossal duct fistula. The midportion of the hyoid bone has been removed. From this point the tract is cored out in the direction of the foramen caecum, which is about a 45 degree angle, with the patient in the goiter position. Dissection is carried up to a point at which the finger at the foramen caecum can be identified, according to the method of Sistrunk. (By courtesy of Surgery, Gynecology and Obstetrics.)

thorough study of cystic hygroma, Emil Goetsch⁸ came to the conclusion that these probably arise from sequestrations of lymphatic tissue derived from the primitive jugular sacs which failed to join the regular lymphatic system. The tumor is a multilocular tumor (fig. 9) lined with endothelium and containing a clear or straw colored fluid, usually located in the neck near the junction of the internal jugular and subclavian veins. Diagnosis is often as easy as the treatment is difficult. These lesions have invasive properties into any and all surrounding structures, making complete removal usually an absolute impossibility, and this, associated with a high susceptibility to infection, results in a rather high mortality. Figi⁹ has recommended irradiation but reports a rather high mortality, and I am inclined to

agree with Fleming¹⁰ and Goetsch⁸ that as complete an excision as possible is the method of choice, except in large tumors in very young infants, in whom radiation might be attempted. I have seen one patient apparently cured following an infection. In that par-

Fig. 9.—Cystic hygroma, showing usual location of the multilocular cystic mass.

ticular case an infection of a cystic hygroma followed a septic throat which necessitated an attempt to relieve the obstructive dyspnea by surgical intervention. Inva-

sion of tiny cysts into the muscles could be noted everywhere well down into the mediastinum and surgical removal was considered most incomplete, yet after a stormy convalescence there is no evidence of tumor tissue five years later.

CONCLUSION

Surgical assault on any congenital lesion of the neck necessitates at least a fundamental knowledge of the embryologic anatomy of the neck. So-called branchial cysts and fistulas are rare, and what are ordinarily called branchial cysts and fistulas should be termed thymic duct cysts and fistulas.

523 West Sixth Street.

ABSTRACT OF DISCUSSION

DR. HERBERT WILLY MEYER, New York: The study of the embryology of the congenital lesions of the neck has always been a fascinating subject. It is an interesting fact that Dr. Wenglowksi, who has probably done more complete work in this investigation than any other author, was a surgeon in Moscow and not an embryologist. His friends, obstetricians and gynecologists, furnished him with seventy-eight embryos ranging in size from 2 to 49 mm. He further performed 144 autopsies on the neck region of infant cadavers and added the study of fifty-nine adult autopsies. Of all of this material he made wax reconstructions and showed the models at the sixth and seventh Russian Surgical Congress. A theory based on such complete and intensive work deserves serious consideration. Wenglowksi studied the branchial apparatus and the development of the neck and such organs as the thymus and thyroid glands. He showed that the branchial apparatus is present in the first and second months of fetal life. Its greatest development is at the end of the first month and it completely disappears by the second half of the second month. The pharyngo-thymic duct develops from the third branchial pouch and passes downward laterally behind the thyroid duct, which develops from the fourth pharyngeal pouch. The two lateral lobes of the thyroid developing from the fourth pouch meet the midthyroid lobe, which descends from the foramen caecum to form the thyroid gland. The two pharyngo-thymic ducts passed downward and forward to meet behind the sternum to form the thymus gland. Normally these ducts disappear completely. If only portions disappear, lateral cysts of the neck develop. If an external opening forms on the skin and the entire duct persists, a complete lateral fistula of the neck develops, emptying into the pharynx through the tonsillar fossa. In the midline, cysts and fistulas of the neck, developing from the lingual duct and the thyroglossal tract, pass downward to the tongue from the foramen caecum. A complete patent tract never is present but only a strand of thickened tissue arising from lingual duct structures or thyroid gland structures. As the hyoid bone develops, it cuts this thyroglossal tract in half by pressure. Frequently gland structures thereby are present under the periosteum and in the midportion of the hyoid bone. Therefore, in order to cure midline cysts and fistulas of the neck, a midportion of the hyoid bone must always be removed and the tract cored out from the tongue. Any cyst or fistula of the lateral portion of the neck above the level of the hyoid bone may be a true remnant of the branchial apparatus. Any cyst or fistula in the lateral portion of the neck below the level of the hyoid must of necessity be a remnant of the pharyngo-thymic apparatus.

DR. CONRAD J. BAUMGARTNER, Los Angeles: I wish to thank Dr. Meyer for his excellent discussion. It is frequently impossible, particularly in children, to invert the stump as shown by previous illustration. I have found it helpful in such cases to have an assistant's finger push outward from the tonsillar fossa in the direction of the dissection. As the finger of the assistant is approached, the stump is severed and ligated.

Heredity and Mental Diseases.—When we consider the nature and etiology of the various mental diseases we become aware of the fact that in less than 40 per cent of the patients admitted to mental hospitals do we find evidence for a hereditary basis, namely, in dementia praecox, manic-depressive, mental deficiency with psychosis, and epilepsy. In the remaining 60 per cent of the patients heredity may play a minor role, but the important etiological factors are probably constitutional (exogenous).—Landis, Carney, and Page, James D.: *Modern Society and Mental Disease*, New York, Farrar & Rinehart, Inc., 1938.

The intravenous use of pentothal sodium in anesthesia has shown a definite and consistent increase since it was first offered in 1934. A five year interval is too short a period after which to assume a final attitude on any anesthetic drug or technic. Nevertheless it is a sufficient interval to indicate logically a way station in its history at which to pause for a critical survey. Therefore it is our aim here to "examine the record" of that which has taken place to date. This examination will include a brief consideration of the literature, certain observations concerning the technic of its administration, and the scope of its rational application in our hands.

LITERATURE

An editorial of a leading surgical magazine¹ in March 1939 aptly stated the present position of intravenous anesthesia: "The increasing usefulness of intra-

venous anesthesia for many types of operations has never been as apparent as it has been recently." This statement may be confirmed further by a perusal of the literature on the subject. More than 100 articles dealing primarily with or touching on the use of pentothal sodium have been published. Medical opinion is found to be predominantly favorable.

In animal experimentation, it has been found that pentothal sodium may produce disturbances of cardiac rhythm.² Conflicting evidence to this statement has also been observed, a brief of which may be presented as follows: A large percentage of animals showed no change in the electrocardiogram, while another group showed disturbances in rhythm and conduction which

ANESTHESIA—RUTH ET AL.

186

were temporary.³ The effect on the heart of human beings was insignificant.⁴ Electrocardiographic tracings were essentially negative.⁵ There were no changes or abnormalities in QRS or T waves.⁶ No changes in rhythm were recorded when the drug was administered without the occurrence of cyanosis.⁷ There was no marked deleterious effect on the myocardium or conductive system of the heart demonstrable by the electrocardiographic record.⁸

Focal necroses have been shown to have occurred in the liver in mice.⁹ It is generally conceded that the drug should not be employed in the face of overwhelming hepatic destruction. Only one instance of hepatic disturbance in man was found to be recorded.¹⁰ In that report it was suggested that there was a possibility that the toxic jaundice which developed after the administration of pentothal sodium to this apparently normal individual might have been a coincidental "catarrhal jaundice."

Attention has been called to the occurrence of temporary closure of the glottis and a hyperactive state of the laryngeal reflex, further complicated by frequent coughing. In addition, hiccups or sneezing may occur. It has been suggested that these phenomena are due to parasympathetic overactivity.¹¹ For this the preanesthetic administration of atropine or scopolamine is shown as an adequate prophylactic measure. One investigation on animals suggests the possibility of cumulative action. In this study¹² a dosage identical with the original was injected whenever the signs of light anesthesia presented. This method of procedure would suggest the possibility of overdose; no anesthetic agent that was required for the purpose of induction, when, during the period of maintenance, the patient appeared in light anesthesia. There is reported no change in the urinary secretion or in the concentration of blood urea.¹³ The blood sugar is reported as being raised somewhat, but not sufficiently to cause any practical difficulty in the control of diabetes.¹⁴ The drug causes an immediate depression of intestinal contraction and tonus. This primary effect was transient and succeeded by a more prolonged phase showing increased intestinal contraction and tonus, which persisted throughout the remainder of the anesthetic period.¹⁵

The use of pentothal sodium for diagnostic tests and for the control of convulsions due to the employment of toxic drugs and to tetanus and eclampsia appears to be of definite value.

A summation of the number of instances of the administration of pentothal sodium to human beings recorded in the literature is difficult of determination. It would seem that its use has been somewhat retarded,

initially, by employment of the method of predetermined and nonfractional dosage formerly recommended for the administration of a comparable drug (evipal soluble). This method of dosage placed definite limitations on the use of either drug until such time as the intermittent method of administration was accepted generally. A further difficulty in estimating the number of administrations was presented by the fact that many reports on intravenous pentothal sodium included, in the statistical portions, an unstated number of patients anesthetized by evipal soluble. Nevertheless, 21,344 instances in which pentothal sodium was administered

intravenously to human beings were located (table 1). Of this group 2,980 are reported in detail in tables 2 and 3.

ADMINISTRATION

The preparation of the patient, the chemical and pharmacologic effects and the preparation and method of administration of pentothal sodium have been heretofore adequately described.¹⁶ These aspects will not

be repeated at this time. Certain factors concerning its administration will be emphasized, however, and additional observations presented at this time.

Prior to the publication of the pharmacologic and physiologic explanation of the value of the administration of atropine or scopolamine before pentothal sodium had been given, it was our practice to administer these drugs preoperatively. They not only effectively counteract the parasympathetic overactivity of this drug but minimize the likelihood of production of excessive secretions. Morphine is prescribed in many instances together with the atropine or scopolamine but always in decreased dosages as compared to those prescribed before inhalation anesthesia. (We regard morphine sulfate one-eighth to one-sixth grain [0.0081 to 0.0108 Gm.] as the maximal dose.) In the aged and debilitated, even though morphine is not administered, and in every instance in which their use is possible, either atropine or scopolamine is administered.

Caution regarding the speed of injection cannot be overemphasized. The patient to whom pentothal sodium is being administered has no active mechanism of defense as, for example, is initiated by the irritating action of ether. The facility with which patients may be anesthetized has proved an ever present temptation to make the induction even more startling by the too rapid administration of the drug. A sacrifice of time will increase the factor of safety. It has been our practice recently either to consume from one to two minutes or more for the induction of anesthesia rather than from twenty to thirty seconds, or at least to pause after the injection of 2 cc. of a 5 per cent solution to estimate the depth of anesthesia produced. Recently a 2.5 per cent solution, instead of the usual 5 per cent solution, has been employed with satisfactory results.¹⁷ This solution further facilitates a slow injection and appears to remove the possibility of the rare occurrence of phlebitis.

It should be emphasized that respiratory depression occurs readily following too rapid administration. No difficulty should be encountered if the administration is continued to the point of anesthetic saturation of the tissues of the central nervous system at a rate sufficiently slow to avoid depressive concentrations being carried to the respiratory center. Experience in its administration is the predominant factor in the problem of timing the rate of injection. It appears that it is a mean between a rapid injection, which quickly depresses the respiratory center, and an injection which is sufficiently retarded so that time is allowed for the drug's detoxification before anesthetic concentrations are produced. The function of respiration must be further protected by diligent maintenance of a patent respiratory tract. Relaxation of the soft tissues about the upper respiratory tract is apt to occur and thereby impinge on its patency. At the same time, obtundation of both pharyngeal and laryngeal reflexes does not occur until quite profound anesthesia has become established. Therefore, when an adequate airway cannot be maintained by proper position of the head, insertion of a nasopharyngeal airway rather than a pharyngeal airway should immediately be carried out. At times, if there is an interference with the efficiency of the respiratory tract, recourse should be had to the usual methods for its rectification which are employed during inhalation anesthesia, which include endotracheal intubation. Cyanosis should never be tolerated by the anesthetist. A source of oxygen under low pressure sufficient to inflate the lungs should be constantly available during the administration of pentothal sodium.

CONTRAINDICATIONS

The contraindications noted elsewhere¹⁸ are recognized by us. The drug is not employed when there is a marked physiologic or mechanical interference with respiratory function. At the present time the drug is employed rarely for patients under 15 years of age and

seldom below 10 years of age. The presence of cardiac dysfunction to the point of dyspnea is recognized as a contraindication. Varicosity central to the point of injection serves as a contraindication or a possibility of slow entrance of the drug into the general circulation after injection is duly noted. Manipulations disturbing pharyngeal and laryngeal reflexes preclude the advisability of employment of this drug, unless other indications for it are real and adequate. In such a

condition, preliminary topical anesthesia of the affected mucous membrane is to be established. A definite deviation from normal in the oxygen-carrying capacity of the blood indicates caution in its application, as for example in the presence of severe anemias. It would not seem wise to employ it in the face of gross hepatic damage, although we found in one instance that the icterus index and bromsulphalein test were unaffected by a forty-minute administration for an intra-abdominal visualization in the presence of massive cancer of the liver.

UNDESIRABLE EFFECTS AND THEIR MANAGEMENT

Sloughing of tissue and irritation at the site of injection may be prevented by the injection of a 2.5 per cent instead of a 5.0 per cent solution. Respiratory depression is rarely a problem with careful and experienced administration but, when present, is best managed by inhalation or inflation of oxygen. Muscular tremors may be annoying, but slow administration usually overcomes them. If not, resort should be made to another agent. Postanesthetic headaches are rare. The fall in blood pressure is minimal. Postanesthetic nausea and vomiting are also rare.

APPLICATION

We feel that pentothal sodium is a valuable drug for operations of short or moderate duration, when extensive muscular relaxation, particularly abdominal, is not required and when there is no interference with respiratory function and laryngeal or pharyngeal reflexes. Its use in our hands is adequately shown in tables 2 and 3.

In addition, we would call attention to its value in our hands in certain supplementary capacities. The first of these is indicated during the operative period under regional or spinal anesthesia, when such is prolonged. Here occasionally the patient may become somewhat uncomfortable as the result of the operative position. This condition is further complicated by a progressive diminution in the effects of the preanesthetic sedation. Here we have found it quite advantageous to administer intermittently minimal amounts, just short of the establishment of unconsciousness. By this means the patient is rendered relaxed and calm and there is a reestablishment of the effects of the original preanesthetic sedation.

Anesthetists are rarely called on today to anesthetize patients suffering from toxic hyperthyroidism who have not been controlled medically before operation. Nevertheless, instances occasionally occur in which preoperative treatment in this condition is of decreased value and it becomes essential to anesthetize these patients with a minimum of preanesthetic disturbance. In such a situation it has been our custom to visit the patient in his room and to state that a blood test is to be performed. After venous puncture, the unsuspecting patient is put to sleep with just sufficient pentothal sodium to enable his removal to the cart. Anesthesia is then continued by inhalation methods. By such means we have been able to remove the patient to the operating room and have the operation started without any evidence of increase in the toxic manifestations of the patient's

disease. Pentobarbital sodium may be used as an alternative agent for this purpose. From 3 to $4\frac{1}{2}$ grains (0.2 to 0.3 Gm.) administered intravenously will usually suffice.¹⁹

The results in thirty-four major intracranial procedures were gratifying. Its application in this respect was initiated by a report that intracranial pressure is not raised by its use²⁰ and by the freedom from hazard of fire and explosion that is provided. Infiltration anesthesia is performed, and pentothal sodium is administered only when the patient becomes tired or restless. Initially, it is injected in similar fashion as described for prolonged operations under regional anesthesia. In several instances it was not necessary at any time to produce complete unconsciousness. This method appeals to us because of its greater controllability as compared to rectal instillations of other agents. The simple apparatus for this purpose is shown in the

Apparatus for continuous intravenous drip between administrations of pentothal sodium.

accompanying illustration. The continuous intravenous drip flows between administrations of pentothal sodium at any desired speed and prevents clotting in the needle. The operating time varied up to five hours and fifteen minutes, with an average time of two hours and forty minutes. The largest single dose was 3.15 Gm., with an average dose of 0.95 Gm. From both surgical and anesthetic points of view we see reason to continue its use in such manner for major intracranial surgery but should state that this portion of the series is too small to be conclusive. It should also be emphasized that its application in this respect was managed only by a highly organized group.

ELECTROCARDIOGRAPHIC AND BLOOD STUDIES

An investigation into possible blood changes was carried out by having tests, the results of which are shown in table 4, performed on the day of, but before

¹⁹ Adams, R. Charles: Personal communication to the authors.

²⁰ Horsley, J. S.: The Intracranial Pressure During Barbitol Narcosis. *Lancet* 1: 141-143 (Jan. 16) 1937.

the administration of, pentothal, immediately following the conclusion of the operation, and in the morning of the first day following its administration. These were completed on twenty-five consecutive unselected patients.²¹ A slight but evidently insignificant rise in the content of dextrose in the blood may be noted immediately following the anesthesia, with a decrease to the preoperative level the next day. Five patients, however, showed a slight immediate decrease. The apparent average rise in blood urea was, to a large extent, accounted for by one patient who exhibited an abnormally high preoperative reading with subsequent additional rise. No changes of any significance were shown in the remainder of the tests performed.

The control of the level of blood sugar is easier than is the control of vomiting which may occur after the administration of other anesthetic agents by inhalation. Since vomiting may lead to the establishment of a diabetic acidosis, it is important to be able to control this untoward reaction by employing pentothal sodium. Patients over 40 years of age may have an associated diabetes and marked cardiovascular disease. It is to members of this group that pentothal sodium must be given with extreme caution.²²

Starr²³ reports that the electrocardiograms taken before, during and after pentothal sodium anesthesia at Hartford Hospital have been examined by him. He states that all the grams were normal and remained normal throughout the experiments. The rates showed only slight change. The PR intervals were not affected. The amplitude, contour and direction of the QRS complexes and T waves showed only slight, inconsequential variations during the test.

SUMMARY

The contraindications to the administration of pentothal sodium are specific. Patients should be carefully selected. Special care should be taken to maintain an efficient airway and one should always be prepared to administer oxygen by inhalation or by insufflation if necessary. The maximal dose of 1 Gm. needs seldom be exceeded. This potent drug should be administered by an anesthetist competent to control all situations that are likely to occur during the administration of any general anesthetic agent. The drug has produced satisfactory results in our hands. No postoperative pulmonary complications were encountered and no operative fatalities occurred. In view of its apparent effectiveness and safety, its growing popularity is warranted and further exploration for possible application among the groups of patients now receiving inflammable anesthetic agents by inhalation seems justified.

ABSTRACT OF DISCUSSION

DR. GEORGE J. THOMAS, Pittsburgh: My experience with pentothal sodium has been very satisfactory, especially the results of electrocardiographic study. At first an electrocardiographic study was made of patients receiving pentothal sodium and carried in the upper surgical plane of anesthesia. The result of these cases showed no change on the myocardium or the conductive system of the heart. Being encouraged by these results I proceeded to study this agent under unusual conditions. For subjects my associates and I took patients with normal

electrocardiograms and gave them a large dose of pentothal sodium. Electrocardiographic study while under this toxic dose showed no change. Five days later electrocardiographic study of the patients showed no latent after-effects. A patient was admitted to the hospital for an operation. He had a coronary attack two years prior to admission. An electrocardiogram showed evidence of bundle branch block due to infarction in the ventricular septum. Numerous premature beats were present. During and after anesthesia, tracings showed no deleterious effect. In fact, following anesthesia the rhythm became regular and the premature beats disappeared. Therefore I feel that the more serious a cardiac condition in a case in which operation is necessary, the more indication there is for pentothal sodium. Preanesthetic medication is an important procedure for a satisfactory intravenous narcosis. I would emphasize the use of the opiates, atropine or scopolamine. We have used pentothal sodium to stop the annoying convulsions that occur under ether anesthesia. As a rule, 2 cc. of 5 per cent solution will stop these convulsions in children. We have used pentothal sodium from five minutes to three hours and fifteen minutes, from 5 years to 85 years of age, from 3 to 69 grains (0.2 to 4 Gm.) in a series of 3,100 cases in the past two and one-half years. We have had no pulmonary complications or death attributed to this type of anesthetic. I agree with the authors regarding the intermittent technic. At St. Francis Hospital we have made this possible and convenient by means of a simple apparatus. For short operations we use the single syringe and a three way stopcock. When the solution in the syringe is depleted we are able to refill the syringe by means of this stopcock. In operations consuming longer than twenty-five or thirty minutes the cannula of the needle frequently becomes clogged with blood clot. Because of this complication we use a manifold to which we attach an ordinary intravenous needle. This makes it possible for us to administer salt solution and pentothal sodium through the same needle.

DR. RALPH KNIGHT, Minneapolis: I quite agree about the danger of muscular spasms of the pharynx and larynx during pentothal anesthesia. At the University of Minnesota we have a good many cases of malignant disease in the region of the mouth and throat. The surgeons constantly asked for pentothal anesthesia for biopsy and often even for destruction of the lesions. Gas anesthesia was impracticable, the contemplated procedure usually seemed too minor to warrant ether anesthesia, and cautery destruction was usually planned. Under pentothal anesthesia, even in the second or third plane of the third stage, in many cases severe spasms of the tongue, pharynx and larynx occurred as soon as the surgical procedure was started, causing respiratory obstruction. Under pentothal sodium, respiratory effort ceases promptly after the occurrence of obstruction. Resuscitative measures were too frequently called for and were sometimes difficult. Often too the surgery proved to be more major than anticipated and it became still more of a problem to maintain an open airway and satisfactory anesthesia. To obviate these difficulties I attempted transnasal blind intubation of the trachea and was surprised to find that it was not difficult under pentothal anesthesia. For a case of carcinoma of the nose I attempted transoral intubation and found it not difficult although it required much deeper pentothal anesthesia than the transnasal method. The first injection of the pentothal sodium must be more rapid than usual to obtain quick throat relaxation; then the injection must be continued, entirely under the direction of the one who is inserting the tube, until the arytenoids and cords relax and the tube can be inserted. This takes not over two minutes as compared with ten to fifteen minutes with gas and ether. As soon as the tube enters the trachea, respiration is usually stimulated. One has complete control, and even should respiration be somewhat overdepressed a few ventilations with oxygen from the machine will restore it to normal. Pentothal sodium with intratracheal oxygen proved to be the ideal anesthetic for these head cases and with this experience we adopted pentothal induction as the routine for introduction of intratracheal tubes whenever they are indicated for any type of surgery, regardless of the anesthetic selected for maintenance. We have now inserted almost 150 intratracheal tubes under pentothal anesthesia.

CLINICAL EXPERIMENTS WITH
ANDROGENSIV. A METHOD OF IMPLANTATION OF
CRYSTALLINE TESTOSTERONESAMUEL A. VEST, M.D.
CHARLOTTESVILLE, VA.AND
JOHN E. HOWARD, M.D.
BALTIMORE

From experimental observations it is well known that androgenic substances are chemically changed and excreted after entering the circulation. The effectiveness of any androgenic preparation depends on many factors. One of the most important, besides the frequency of administration and the dosage, is the method of administration. The use of various solvents, the addition of fatty acids to the androgenic solutions, esterification of the substances and many other variations have been studied in an attempt to increase the efficiency of administration of androgenic substances. The fact that pure crystalline testosterone is readily absorbed by the body fluids undoubtedly leads to waste when excess material is given. In order to overcome this difficulty and to decrease the rate of absorption, testosterone has usually been injected in an oily solution as the propionate. Injection of testosterone propionate has proved far more effective than the equivalent amounts of free testosterone. The intensity and duration of the action of testosterone has been thus enhanced, and treatment of hypogonadism in human beings has been satisfactorily carried out with injections at intervals of from three to four days.¹ From the results of animal experiments it would appear that when large amounts of testosterone propionate are injected at such intervals an appreciable proportion of the substance is wasted. Testosterone has also been used clinically in the form of innuncions and by oral administration. It is not entirely satisfactory in the form of innuncions and when given by mouth enormous amounts are necessary to elicit clinical response. A method of administration which would tend to simulate the secretion of this hormone by the testis has been sought. If androgenic substance can be administered so that the amount absorbed daily is not in excess of the physiologic requirements, waste will be eliminated and expense can be kept to a minimum. Before the prevalent intramuscular injection of the testosterone propionate in an oily solution is supplanted, a new method must prove to be more convenient, more efficient, less expensive and devoid of harmful consequences.

The first use of pure androgens and estrogens by subcutaneous implantation of crystals or pellets was reported by Deanesly and Parkes² in 1937 and 1938. Their work indicated that tablets of compressed crys-

tals implanted subcutaneously produced stronger and longer effects of stimulation than similar doses given by injection. Schoeller and Gehrke³ later showed the superior effect of implanted testosterone and testosterone propionate tablets in fowls. Having knowledge at the time of the work that Deanesly was carrying out in experimental animals, we first implanted pellets of crystalline testosterone subcutaneously into a patient with hypogonadism in the fall of 1937, but these pellets were too small to produce any significant clinical results. Three recent reports⁴ have referred to the

Fig. 1.—The instruments used to make pellets of various sizes. A, the press; B, the die with three sizes of pellets; C, the punches; D, the assembled press with a punch in place; E, the heavy metal mallet.

From the James Buchanan Brady Urological Institute and the Department of Medicine of the Johns Hopkins University and Hospital.

This work has been aided by a grant from the Ciba Pharmaceutical Products, Inc., which also supplied the testosterone, and by a fellowship from the Lalor Foundation.

This method was presented in brief in a discussion before the Section on Urology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

tion of moderate sized pellets of desoxycorticosterone acetate, we began to make and implant pure testosterone in large pellets weighing up to 800 mg. We have now implanted these pellets into a series of thirteen patients with hypogonadism.⁶ We have implanted pellets subcutaneously or intramuscularly in the leg, arm, back

Fig. 2.—A, the "injector" instrument with fenestra closed; A', the mechanism to open and close fenestra at will; B, three sizes of pellets; C, instrument with fenestra opened by rotating handle (note the blade-like point); D, end of injector showing obturator extruding a pellet; E, same as D but with two pellets being extruded.

and scrotum. The pellets have been removed later and reweighed in order to calculate the average amount that has been absorbed daily. The actual curve of absorption probably shows a gradual decrease as the size of the pellet becomes smaller. Tissues surrounding the pellets, which are foreign bodies, have been removed and studied pathologically. Assays of the urinary androgens and estrogens have been made before and after implantation. A systematic study of various aspects of pellet implantation with both crystalline testosterone and some of its esters is now being completed and an evaluation of the clinical results will be discussed in a forthcoming report.⁷ A study of the effects of testosterone and its esters in the monkey, comparing the method of injection with the implantation of pellets, is also in progress.⁸

Our purpose in this report is to present a new technic for the subcutaneous implantation of solids such as pellets of pure crystalline androgenic substance by the use of an "injector" instrument.⁹

If the slow absorption of subcutaneous androgenic substance in pellet form was to be more efficient per unit weight of material utilized, this advantage would be offset somewhat by the impracticability of the necessary incision for implantation. To obviate an operating room procedure, the following method was devised. Figure 1 A, B and C shows the press, die and punches used to make pellets of three different sizes. The pellets are shown in their corresponding slots. Figure 1 D

shows the assembled press with a punch in place. Figure 1 E shows the heavy metal hammer used to pound the previously sterilized, powdered testosterone into a very hard and compact pellet. These implements can be boiled and the pellets are made under sterile technic. It has been impossible to make pellets of uniform size and weight with such an apparatus, but for practical purposes it has served for our study. Many factors probably affect the absorption rate, the foremost of which are the surface area and the density of the pellet. Other possible factors are the vascularity of the site of implantation, the extent of the reaction to the foreign body and the degree of hormone deficiency. For absolute comparative values regarding absorption and clinical effect in a series of cases it would have been ideal to implant pellets of identical size and weight, but this was not possible.

Figure 2 A shows one of several instruments which we have devised on the principle of the syringe in order that solid pellets might be injected subcutaneously or intramuscularly in the office instead of in an oper-

Fig. 3.—Method of depositing pellet by means of a new "injector" instrument. an instrument to date is two pellets of more than 400 mg. each at one time. Figure 2C shows the instrument with the fenestra open and the obturator withdrawn. Figure 2D shows the end of the "injector" or "implanter" with the fenestra open through which the obturator is extruding a pellet. Figure 2E shows how

because the margins of the skin of the 6 to 8 mm. puncture wound usually approximate themselves.

The following two cases are reported as examples of the clinical activity of testosterone when it is implanted into man in the form of pure crystalline pellets of large size:

CASE 1.—History.—W. A., a white youth aged 21, admitted to the James Buchanan Brady Urological Institute March 21, 1939, complained of having "never matured sexually." His two brothers developed normally. The usual changes of puberty, with the exception of the appearance of a few pubic hairs at the age of 15 to 16, did not occur in the patient. He stopped school in the eleventh grade because of his underdevelopment. His psychologic content was definitely male. Erections had occurred frequently in the mornings since the age of 17, and he masturbated several times a year but without ejaculation.

Examination.—Figure 4A shows the typical eunuchoid appearance. The patient was 5 feet 10½ inches (149 cm.) tall and weighed 142¾ pounds (64.8 Kg.). Roentgenograms showed a normal skull and sella, but there was retardation in the epiphyseal closure of the bones. There was more than 25 but less than 50 rat units of follicle stimulating factor per liter of

Fig. 4 (case 1).—Appearance of patient, aged 21, with hypogonadism before and after implantation of pellets of crystalline testosterone in muscle of back. A, full view and genitalia before implantation; B, same ninety days later.

two pellets can be injected, one following the other. The obturator can be entirely withdrawn and the pellets inserted into the proximal end of the barrel as desired instead of through the open fenestra. The fenestra can be opened and closed at will by means of the rotary barrel mechanism controlled at the handle.

The instrument is used in the following manner, as shown in figure 3. A wheal is made in the skin of the thigh with a solution of nupercaine. The instrument with the pellets of testosterone inside and the fenestra closed is pushed painlessly through the skin and, if desired, beneath the fascia lata (fig. 3A). In figure 3B the fenestra has been opened and the obturator is being pushed forward to extrude the pellets in the muscle of the thigh. The fenestra is then closed and the instrument is withdrawn, leaving the pellet in place as shown in fig. 3C. A silver clip has been used to close the puncture wound. A clip is not always necessary

Fig. 5 (case 2).—Appearance of patient, aged 34, with hypogonadism before and after implantation of large pellet of testosterone weighing 750 mg. into scrotum. In some respects this could be termed a "synthetic testicle." A, full view and genitalia before implantation; B, same two and one-half months later. Slower absorption of large pellet in scrotum was taking place as compared to case 1.

urine. No hair was present on the face, extremities, abdomen or chest. The breasts were normal. The voice was high pitched. The penis was infantile (fig. 4A) and only 5 cm. long on complete extension. The testicles were about 4 to 5 mm. in diameter and were situated in the scrotum. The outlines of the prostate and seminal vesicles were impalpable. No secretion was expressed by massage of the prostatic region.

Treatment.—March 25 three pellets of crystalline testosterone weighing 277, 219 and 175 mg. were implanted in the right lumbar muscles. (In this case we used three relatively small pellets instead of one or two large ones because we wished to study the absorption rate of pellets of this size compared with the larger ones.)

Result.—The second day after implantation the patient began to notice an increased frequency of erections and he masturbated eight times in the subsequent three months. Ejaculation occurred for the first time in his life. The nipples soon became tender with the appearance of small lumps underneath, more marked on the left. At the end of the first month the voice began to

have found in other patients who received a single large pellet. The patient is now continuing to develop with a single pellet weighing 778 mg.

CASE 2.—History.—J. R., a man aged 34, entered the James Buchanan Brady Urological Institute April 1, 1939. His brothers were normally developed. At the age of 15 the patient had his present degree of pubescence. Since then he had had an occasional erection, with rare masturbation without ejaculation.

Examination.—The patient presented a eunuchoid appearance. Figure 5A shows the patient before treatment. He was 5 feet 5¾ inches (167 cm.) tall. A roentgenogram showed delayed union of the epiphyses with the skeletal age of a youth 18 years old. There was present 25 rat units of follicle stimulating factor per liter. The genitalia were undeveloped (fig. 5A). The penis was 4.5 cm. long on complete extension. The testes were 1 cm. long and were situated in the upper part of the scrotum. Considerable pubic, rectal and perineal hair was present. No hair was present on the chin, body or extremities. A tiny amount of prostatic tissue could be felt around the urethra. The seminal vesicles were indefinite. No secretion could be expressed by massage.

Treatment.—April 10 a pellet of pure testosterone weighing 750 mg. was implanted into the scrotum. The scrotum was selected because of its superficial position where the pellet could easily be palpated from time to time. It is possible that absorption from the scrotum is slower and not as satisfactory as from muscle or subcutaneous tissue.

Result.—Figure 5B shows the patient's appearance two and one-half months after implantation, at which time it seemed by palpation that only about one third of the pellet had been absorbed. During this time he complained of erections practically all night and frequently during the day. The testes descended to the bottom of the scrotum so that the left came to lie just adjacent to the pellet. The voice became deeper. He gained 4 pounds (1,814 Gm.) the first two weeks and 3 pounds (1,307 Gm.) the following two weeks. He began to masturbate three or four times a week, with ejaculation. Slight tenderness appeared in both breasts, especially the left. Hair began to grow on the lower legs and the upper lip. In two and one-half months (fig. 5B) the penis had increased in size and was now 6.3 cm. in complete extension. The prostate had developed to about two thirds normal size. It was normal in contour, shape and consistency. Several drops of secretion could be expressed which were normal in appearance and normal microscopically. The seminal vesicles were easily palpable and almost normal in size.

The clinical results, though just beginning in these patients, is indicative of the activity of crystalline testosterone when implanted subcutaneously in the form of pellets. The method may prove to have important clinical applications, but more extensive work is necessary to establish this with certainty.

It has been of interest to study the type of tissue reactions which occur around pellets of testosterone. Figure 6A and B shows photomicrographs of the tissue encapsulating pellets four months after implantation. In figure 6A the cavity in which the pellet was situated is visible. Surrounding this cavity is granulation tissue containing many foreign-body giant cells, an occasional leukocyte and some round cells, all lying in a fibroblastic matrix. In 6B (another case) there is less reaction to the foreign body, with only a rare giant cell. Much fibrous scar tissue has developed, some of which is hyaline. A dense collection and some diffuse round cells are seen. There is no evidence of unusual cellular reaction, metaplasia or carcinogenic activity.

It is possible that such an instrument as we have developed and presented here might be applicable to injection of other solid medicinal materials.

University Hospital, Charlottesville, Va.—24 East Eager Street, Baltimore.

fig. 6.—Sections of tissue showing reaction around cavities where pellets had been placed for three months in the subcutaneous tissue of arms of two patients. A, many giant cells with some round cells and leukocytes; B, fibrous tissue, some of which is hyaline, and a dense collection of round cells.

crack and assume a lower pitch. At the end of three months (June 23) a distinct increase of pubic hair had occurred, together with the appearance of profuse, thin, short hairs on the lower legs. The scrotum became larger and darker. The prostate was then three fourths of the normal adult size and of normal consistency and contour. The seminal vesicles were, however, barely palpable. Normal prostatic secretion was expressed. The penis increased in diameter and when completely extended measured 8.5 cm. Figure 4B shows the patient's appearance June 23, ninety days after the pellet implantation. During this period he absorbed the three pellets completely, an average of at least 6.9 mg. a day. Pellets of this size absorb rapidly; his absorption rate was approximately twice that of what we

THE PROTECTION OF CHILDREN
FROM TUBERCULOUS ADULTS

FAIRFAX HALL, M.D.

NEW ROCHELLE, N. Y.

There is a definite hazard to the health of children from intimate association with persons about whom little or nothing is known with regard to freedom from tuberculosis or other communicable conditions. Since parents are much more apt to have had adequate medical supervision than the servants in a home, the risk to children from the latter is greater. Occasionally an older member of a family, mistakenly thought to have "chronic bronchitis" or "asthma," is a factor to be considered in safeguarding a child from tuberculosis. School teachers with active tuberculosis are a menace to their pupils.

The New York Tuberculosis Association in 1922, through the instigation of Dr. Charles Hendee Smith, made a study of the subject of protecting children from tuberculous servants.¹ It was stated that "every stranger who comes into our household carries an insidious threat against our nearest and dearest, the children," and "it is high time to combat this very real danger." It was concluded that all persons in contact with children should undergo periodic medical examinations.

It is unnecessary to detail the several instances among my patients in which a primary tuberculous infection was acquired from a servant or other member of the household. Every physician with experience in the care of children knows of instances in his own practice of primary tuberculosis from exposure to tuberculous adults in the home. With a few of my own child patients infected in this way the outcome was tragic. In others the tuberculin reaction was positive without clinical evidence of pulmonary lesions during childhood.

A large number of children in whom the tuberculin reaction was positive before 7 years of age were followed for 11 years by Ch'ui, Myers and Stewart.² Nine times more of these children developed the reinfection type of disease than did those of a control group in whom the tuberculin test was negative at the same age. This is conclusive evidence of the potential danger to the future health of a child when the tuberculous infection is acquired early. It shows that a positive tuberculin reaction in childhood is undesirable and may be a more serious matter than a positive Wassermann reaction.

The fact is, practically all childhood tuberculosis is contracted from association with adults who have the disease in an open form. I agree emphatically with Dietrich³ that to prevent the contact of tuberculous persons with children is as worthy a project as was that to eliminate tuberculous dairy cattle from the production of milk. By proper foresight and appropriate action this can be done.

At the time when C. H. Smith¹ made the attempt to attack the problem of the tuberculous servant he encountered many difficulties which are still present,

although possibly to a less degree. The public is now more fully aware than in the past of the danger to children from contact with open tuberculosis. This and the campaign of education regarding syphilis have made parents willing and anxious to keep diseases of a communicable nature out of their homes and away from their children.

Prevention of contact between children and tuberculous nursemaids or other domestic helpers will be less frequent when parents are so convinced of the necessity of employing only healthy servants that they will demand proof of their servants' health. Too frequently a great deal of resistance has to be broken down and prejudices overcome before servants can be induced to submit to this procedure. Domestic helpers having to do with the care of young children must be persuaded that it is to their advantage to have periodic medical examinations so that they will secure them as a matter of course. When "health references" are universally asked for and a health card is essential to get a job, a great step forward will have been made. Physicians interested in child health should influence their patients to take this wise precaution for the sake of the children.

The danger to children from a tuberculous school teacher is illustrated dramatically by the case of a teacher in Minnesota reported by the Jordans.⁴ This teacher, with unrecognized far advanced tuberculosis, in addition to teaching chemistry instructed the band and orchestra. Often he would blow into a child's instrument, showing him how to execute a difficult passage. The child then returned it to his own lips, with a definite sputum transfer. It was found that 33½ per cent of the boys of the band reacted positively to the Mantoux test while the pupils of the school as a whole were 15.72 per cent positive, a 100 per cent greater incidence among his pupils.

The teachers and janitors in this school were 49 per cent positive to the Mantoux test. Five of the 173 examined had reinfection adult type pulmonary tuberculosis.

In a tuberculosis survey in Macon County, Ill.,⁵ of 705 school teachers given x-ray examinations 315 were found to be infected and nine were actively tuberculous. Lindberg concludes with the statement that "while the school teacher has not more tuberculosis than the average adult, next to the family she provides the greatest opportunity for close prolonged contact with the school child. To require the teacher to provide a health certificate, including chest films, would serve to remove this reservoir of infection."

As a result of tuberculin tests and x-ray examinations of more than 6,066 school teachers in a survey in several parts of the country, 2.15 per cent were found to have tuberculosis in a stage requiring treatment. On this basis Lees⁶ concludes that among the 871,607 teachers in our elementary and secondary schools 18,739 tuberculous teachers were in active service in 1936. This statement was confirmed by Myers.⁷

L. S. Jordan⁸ maintains that the prevention of infection is the primary step in the control of tuberculosis.

Read before the region I meeting of the American Academy of Pediatrics, New York, June 1, 1939.

8. Jordan, L. S.: The Teacher, *Journal Lancet* 56:187 (April) 1936.

"Find the source" was his slogan. He found the sputum positive in eight of 786 teachers tested. He reported further that of sixty-four pupils exposed to a teacher with far advanced pulmonary tuberculosis 42.6 per cent were positive to the Mantoux test, while of 161 other pupils of the same school and age group 11.2 per cent were positive. This is definite evidence of the increased incidence of infection resulting from contact with a teacher having open tuberculosis.

The approach, methods employed and results of a tuberculosis survey of teachers and janitors in the schools of Minneapolis sets an example which can well be followed by any community which has not already established a satisfactory system of its own. This is described by Harrington, Myers and Levine⁹ in reporting the examination of 3,600 Minneapolis school employees. Sixty-eight showed x-ray evidence of disease necessitating further observation. Six were found to have tubercle bacilli in their sputum.

In 1930 Dietrich⁸ reported three families in which four children developed tuberculosis (two of them died) following contact in their homes with tuberculous nursemaids. He also told of a kindergarten teacher with active pulmonary phthisis whose association with her 5 year old pupils resulted in the primary tuberculous infection of several of them. Dietrich found at that time that there were laws in five states requiring teachers to be free from tuberculosis and no laws in respect to the health of nursemaids and governesses. He recommended health examinations for all nursemaids, governesses and kindergarten teachers and issuance of cards to all healthy applicants.

Rogers¹⁰ in 1934 summarized all aspects of the care of teacher health in this country as follows: About two thirds of the largest cities required a certificate of health from teachers before appointment. The smaller the community, the fewer had such a regulation. At that date, in twenty states, examination before employment was required by law. Nowhere was a tuberculin reaction or lung x-ray examination mentioned as a requisite part of the examination. In few, if any places was repetition of examinations at stated intervals part of the health program for teachers. When free medical consultation service was offered, teachers seldom made use of it, probably because of fear that the result of an examination might react to their disadvantage.

One cannot help concluding that, for school teachers to be proved healthy and free from transmissible disease, medical examination must be compulsory and repeated at regular intervals. These examinations should include a tuberculin test and x-ray examination of the lungs and should be made by a physician who is uninfluenced by any personal considerations which might affect his report. In 1934 Philadelphia was the only city with a teacher health program approaching this ideal. Recently New York City has required thorough examination of new teachers with periodic reexamination.

The American Academy of Pediatrics has endorsed the principle of healthy adults in contact with children. A campaign is in progress to bring to the attention of doctors, parents, servants, trained nurses and teachers facts relative to this aspect of child health. Through its

Committee on Contact Infections, with the assistance and cooperation of many child health minded organizations, the program of education is under way. Pediatricians and family physicians can accomplish a great deal by advocating that parents, other members of the family, servants, nursemaids and trained nurses, because of their intimate contact with children, should have periodic health examinations.

County and other medical societies throughout the country are sponsoring a standardized examination designed to detect any contagious condition. The examination will include an x-ray examination of the lungs, at least for all who are tuberculin positive. The examination will be available at a low rate of charge. In most instances the radiologists are cooperating by charging a minimum fee for the chest film.

The American Academy of Pediatrics advocates that examinations be undergone voluntarily, through an appeal to reason, rather than from compulsion. What provision is made for obtaining examinations will depend on the conditions existing in each locality. It is desirable that examinations of all who are employed be made by practicing physicians. In communities where the wage scales of domestics do not permit the payment of a fee sufficient to compensate a doctor for the time required for an adequate examination and for an x-ray examination, the applicants will be examined in clinics for a nominal fee or no charge.

As part of this program for examination of domestic servants in Knoxville, Tenn., Dr. Oliver W. Hill¹¹ reports that, in 1938, 571 persons with syphilis, sixty-seven with active tuberculosis and five typhoid carriers were picked up and put out of circulation.

Finding persons with insufficiently or untreated syphilis is an important feature of this project. It is thought that the benefit from this will be greater to the individual needing treatment than to the children with whom they are associated. The communicability of this disease to children through kissing is possible, though infrequent, when compared with tuberculosis, in which the contagious stage lasts for a much longer period. Smith¹² was able to collect but 125 cases of acquired syphilis in children under 11 years of age.

There can be no question that this program will be advantageous to the health of children by protecting many of them from unnecessary illness. In addition, the individuals examined may have much to gain through the discovery of conditions needing medical attention.

The practicing physician is the person to take the lead by advocating this health protection. The success of the program depends to a great extent on his recommendation. The physician can go even further in setting an example by himself having a physical examination and an x-ray examination of the lungs.

CONCLUSIONS

1. Tuberculosis in children is acquired almost exclusively from contact with infected adults in their homes and in school.
2. School teachers should be proved to be free from communicable tuberculosis. In very few communities in this country is this being done.
3. Domestic servants and nurses should have periodic medical examinations and be required to furnish a "health reference" of freedom from transmissible disease.

12. Smith, F. R., Jr.: Acquired Syphilis in Children, *Am. J. Syph., Gonorr. & Ven. Dis.* 23: 165-185 (March) 1939.

4. Parents, relatives and pediatricians should also be examined at intervals.

5. Cooperation with the program of the American Academy of Pediatrics for healthy adults in contact with children will result in fewer cases of childhood tuberculosis infection.

Clinical Notes, Suggestions and New Instruments

RAPID RECOVERY FROM TYPE XIII LOBAR PNEUMONIA TREATED WITH RABBIT SERUM

OF A PATIENT WITH ADDISON'S DISEASE UNDER TREATMENT WITH DESOXYCORTICOSTERONE

FORD K. HICK, M.D., AND BRODA O. BARNES, M.D.
CHICAGO

This report is made to change a conception of prognosis in Addison's disease complicated by infection. Undoubtedly, many physicians have seen patients with Addison's disease survive infections. Usually such subjects are treated as though they were in crisis. This man had been controlled with desoxycorticosterone and had returned to work when seized with lobar pneumonia. He was continued on the same dose of the synthetic hormone plus 5 cc. of adrenal cortex extract¹ daily and made a rapid, complete recovery.

We feel that this result further confirms the efficiency of the substitution therapy with desoxycorticosterone in Addison's disease and that infection should not upset these patients too much, provided a specific treatment is available for the infection.

REPORT OF CASE

A white man of 38, a salesman, entered Henrotin Hospital May 8, 1939, with the complaint of weakness, dizziness, loss of appetite and loss in weight. He had been well until the fall of 1938, when he began to grow weaker and to eat poorly. His symptoms were considerably aggravated by influenza in February 1939, when he was away from work one month because of weakness. Dizziness came on standing up suddenly, on moving about or with exercise. On a few occasions he had fallen. Lying down always put an end to the dizziness. His weight had gone from 148 to 130 pounds (67 to 59 Kg.) on entrance since November 1938. There was a considerable aversion to food, and nausea was frequent this spring. He had not vomited or had severe abdominal pain.

The past history was irrelevant except that he had been sick for a few weeks with pneumonia at the age of 20.

The patient was a slender man, not acutely ill, with considerable brown pigmentation about his head, which was bald, and the neck, arms and sides of the body, especially the lateral aspect of each hip. His strength was fair in the arms and legs.

The blood pressure was found to be 60 systolic, 40 diastolic standing up and 78 systolic, 50 diastolic while sitting up. While lying down the lowest figure was 86 systolic, 56 diastolic. The laboratory work-up showed no abnormality save that the serum sodium was 133 milliequivalents per liter, compared to the normal of 140 or more.

Treatment was started with 10 cc. of adrenal cortex extract and 4 Gm. of salt daily. There was marked subjective improvement. His weight began to increase as his appetite returned. After six days on this treatment he was placed on 5 mg. of desoxycorticosterone subcutaneously each day, on which his weight came up to 138 and his blood pressure stabilized at about 120 systolic, 80 diastolic, and he returned to work.

June 23 he had a slight nasal discharge and fulness in the head. The blood pressure was 114 systolic, 80 diastolic, while standing. Next morning at 2 o'clock he had a chill and vomited twice. On returning to the hospital at 5 a. m. he was acutely ill.

The temperature was 104.4 F., pulse rate 100, respiratory rate 30 and blood pressure 146 systolic, 90 diastolic. The accessory muscles of respiration were in use. There were questionable harsh breath sounds over the left lower lobe posteriorly. He was given 1,000 cc. of 5 per cent dextrose in physiologic solution of sodium chloride.

The sputum contained type XIII pneumococci and antiserum was started at 1 p. m., 200,000 units of rabbit serum being given undiluted by 8 p. m. The white count was 7,200, the blood culture negative.

June 25 the peak temperature was 99.4 F., the blood pressure 120 systolic, 72 diastolic. The patient felt well but coughed up a little bright red sputum. He had no more fever but showed dulness and rales over the left lower lobe for two days. An x-ray examination confirmed the diagnosis of lobar pneumonia. Retyping the sputum showed the same organism.

The management of Addison's disease during the pneumonia was 1 Gm. of salt daily, a general diet along with desoxycorticosterone 5 mg. daily subcutaneously, and 5 cc. of adrenal cortex extract for four days. The maintenance dose of 5 mg. of desoxycorticosterone daily is again adequate. The patient returned to general activity June 29.

1853 West Polk Street.

SUMMARY OF SOME CLINICAL STUDIES ON VITAMIN K

ERIK TAGE-HANSEN, COPENHAGEN, DENMARK

In continuation of the work of Dam and Glavind¹ I have in the past year carried out a series of investigations on patients with diseases in which lowered prothrombin might be expected. The determination of prothrombin was made by the method described by these authors. It was found to work satisfactorily. In fourteen of the cases in which lowered prothrombin (high R-values) were found, the different ways of administering vitamin K were also studied.

Dam and Glavind¹ reported the treatment of five cases of obstructive jaundice with K-avitaminosis by intramuscular injections of an emulsion of vitamin K in water and found it possible to restore the blood coagulation to the normal value within a week.

Since then I have studied the effect of vitamin K when given perorally, intramuscularly and intravenously.

For peroral use gelatin or starch capsules containing the concentrate together with desoxycholic acid were prepared. In accordance with the studies of Butt, Snell and Osterberg,² normal coagulation was obtained within two days with doses of from 100,000 to 200,000 Dam units of vitamin K plus 2 Gm. of desoxycholic acid. Some days later the coagulation defect began to set in again.

By ingestion of an emulsion of the vitamin in sodium desoxycholate solution by duodenal or stomach tube the same effect was obtained.

For injection purposes, concentrates having a strength of more than 1 million units per gram were used.

Intramuscular injection on two successive days of a watery emulsion of such a preparation representing 150,000 units of vitamin K resulted in normal coagulation three days after the first injection, an observation which is in accordance with the results reported by Dam and Glavind.

Intramuscular injection of an oil solution of the vitamin in a one day or in a three to five day period led to restoration of normal blood coagulation after one to two weeks, from 150,000 to 400,000 units in all being used for each patient. In some cases in which surgery was not employed, it could be shown that the effect lasted for at least three weeks.

Læger* 100: 248-250 (March 10) 1938; Vitamin K in Human Pathology, *Lancet* 1: 720 (March 26) 1938; The Clotting Power of Human and Mammalian Blood in Relation to Vitamin K, *Acta med. Scandinav.* 96: 108-128, 1938.

2. Butt, H. R.; Snell, A. M., and Osterberg, A. E.: Further Observations on the Use of Vitamin K in the Prevention and Control of the Hemorrhagic Diathesis in Cases of Jaundice, *Proc. Staff Meet., Mayo Clin.* 13: 753-764 (Nov. 30) 1938.

From the University of Illinois College of Medicine and Henrotin Hospital.

1. The substance used was Wilson Laboratories "Cortin."

Intravenous injection of emulsions—from 15,000 to 30,000 units in one dose—yielded normal blood coagulation within eighteen hours, but as in the case of peroral introduction the effect persisted for only a few days.

The foregoing results are in accordance with corresponding experiments on animals.

Similar results have been obtained with all three forms of administration against the hypoprothrombinemia of newborn and older infants suffering from icterus gravis neonatorum and certain related diseases.³

In urgent cases it is a great advantage that two rapidly acting forms of application are now available: intravenous injection and ingestion together with bile, of which the first is the most efficient.

The intramuscular injection of oil solutions is remarkable for the long duration of the effect.

The proper treatment of each case is rendered possible by taking advantage of the different modes of application, preferably by a suitable combination of them.

TYPE SPECIFIC POLYSACCHARIDE SKIN TEST IN SERUM THERAPY OF PNEUMONIA

CLINICAL LECTURE AT ST. LOUIS SESSION

JOSEPH C. EDWARDS, M.D.

CHARLES L. HOAGLAND, M.D.

AND

LAWRENCE D. THOMPSON, M.D.

ST. LOUIS

The application of the intracutaneous test with type specific pneumococcic polysaccharide as a guide in serum therapy rests on a basis as sound theoretically as that of the Schick test in the measurement of dermal resistance to diphtheria toxin. In the case of the pneumococcus polysaccharide a positive reaction indicates resistance to the pneumococcus, while in the Schick test a positive reaction is indicative of a lack of such resistance. In either case, however, dermal reactivity is used as a criterion of the immune status of the whole organism.

That pneumococci are not alike was an observation made in 1897 by Bezançon and Griffon,¹ who reported serologic differences among morphologically indistinguishable pneumococci. Briefly, the intact pneumococcus cell may be considered to exist as a body, or soma, of bacterial protein, surrounded by a discrete capsule consisting of a carbohydrate substance of relatively complex structure. When released from the intact pneumococcus cell, this material is water soluble and may be precipitated from autolyzed cultures by

appropriate concentrations of alcohol or acetone, following in general the precipitation reaction of all complex soluble carbohydrates.

It was the significant discovery of this capsular material, or the so-called soluble specific substance, by Dochez and Avery in 1917² that has led to a more or less exact understanding of the qualitative differences existing among the thirty varying types of pneumococci.

The intensive studies of Heidelberger, Avery, Kabat and Goebel³ have given more exact information concerning the structure of certain of these type specific polysaccharides and their relation to specificity. The capsular material of the common groups, at least of types II, III and VIII, appears to be composed of dextrose and glucuronide units (aldobionic acid) in a carbohydrate chain. Type I contains, as a basic group, a trisaccharide with the two uronic acid molecules and an amino sugar.⁴ Until recently it was believed that the uronic acid group was common to all pneumococci and formed a basic antigenic unit. The structure of type XIV, however, does not conform to this concept, in that it is composed of hexosamine units with no demonstrable trace of uronic acid.⁵ In the case of II, III and VIII the difference appears to be chiefly one of stereochemistry, or the arrangement of the basic unit in space.

These polysaccharides when coupled with a more or less common pneumococcus protein form complete antigens. The orientation of the antigenic action in the production of antibody, however, is a function of the carbohydrate group comprising the capsule. Although in most animals the material depends on the protein portion for its complete antigenic action, it will, in its chemically pure form, react by precipitation with homologous antipneumococcus serums in dilutions as high as 1 to 4,000,000. Felton has studied its value as a vaccine.⁶

For use in skin testing only chemically pure capsular material can be employed. Much of the earlier work is equivocal, owing to the fact that impure carbohydrate substances were used. The pneumococcus contains, in addition to its type specific capsular polysaccharide, a so-called somatic, or C, fraction, which is nonspecific and may give a latent reaction directed against the nonspecific, or somatic, antibody. In addition, the somatic substance contains yeast nucleic acids and nucleoproteins which are severe skin irritants and often contaminate improperly prepared capsular material. A report of the more detailed technic employed by one of us (C. L. H.) in the isolation of the pure carbohydrate fractions will be published later. White, Robinson and Barnes discussed the various methods thus far employed.⁷

From the Department of Internal Medicine, Washington University School of Medicine.

The work was made possible by grants to the Washington University School of Medicine from Eli Lilly & Co., Indianapolis.

Read in the General Scientific Meetings at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 15, 1939.

The visiting and resident staffs and the laboratory personnel of St. Louis City Hospital, Barnes Hospital, St. Louis County Hospital, Jewish Hospital, St. Luke's Hospital and St. Mary's Hospital and the Department of Health of the City of St. Louis cooperated in this study. Eli Lilly & Co. supplied antipneumococcus rabbit serum and certain of the pneumococcus cultures from which Dr. C. L. Hoagland extracted the polysaccharides.

1. Bezançon, F., and Griffon, V.: Pouvoir agglutinatif du serum dans les infections expérimentales et humaines à pneumocoques, *Compt. rend. Soc. de biol.* 49: 551, 1897.

The rationale of the skin test itself rests on the observations of Mackenzie and Woo⁸ in 1925 of an allergic condition in the skin of guinea pigs following immunization by killed pneumococci. That the mechanism might be used as a guide in serum therapy was suggested in 1933 by Francis,⁹ who observed that 100 per cent of patients with type I pneumonia developed at the time of crisis an urticarial wheal following the intracutaneous inoculation of a dilute aqueous solution of type I capsular polysaccharide. In an earlier communication Tillett and Francis¹⁰ had observed that the skin reaction to capsular polysaccharide appeared in many patients after treatment with homologous anti-pneumococcus serums and that when such reaction occurred the prognosis was excellent. The fact that the reaction appeared quickly, sometimes within thirty minutes after serum administration, made it a desirable method of ascertaining when an adequate amount of serum had been administered without waiting for the drop in temperature and the clinical improvement which formerly were the only guides to adequate serum therapy.

It has been established by the work of Freund¹¹ and others that the skin is the last organ to become sensitized after the parenteral administration of immune serums. This knowledge is particularly applicable to the use of the skin test in the control of serum dosage, since a positive reaction must indicate complete organic saturation with antibody, a therapeutic ideal. That the skin test is also applicable to patients treated with horse serum as well as with rabbit serum has been established by MacLeod, Hoagland and Beeson¹² and Finland and Sutliff.¹³

CLINICAL STUDY

A total of 114 patients were treated with type specific antipneumococcus rabbit serum¹⁴ in several hospitals. Both serum and polysaccharide were available for types I, II, V, VII, VIII and XIV. In addition, we had polysaccharide for types III, IV and VI. It was confirmed by clinical trial that all were free of the C substance.

In an effort to make the study uniform, all the patients were examined by one of us, who viewed the roentgenograms, supervised the administration of serum and performed the polysaccharide skin tests before, during and after serum administration. Each serum was monovalent and was given intravenously by a method to be described in another report.

Technic of the Skin Test.—In each case 0.05 cc. of a dilution of 1:10,000 type specific polysaccharide in physiologic solution of sodium chloride is injected intracutaneously on the flexor surface of the forearm, and the edges of the wheal so raised are sharply dotted with ink to enable one to detect the slightest alteration

in contour or elevation after fifteen minutes. This is usually injected at the time of the tests for sensitivity to serum but may be delayed until after the intravenous test dose. If the rest of the serum is given in one or two doses within the next hour or so, there will usually be enough polysaccharide at the site of the previous test to react when sufficient serum has been given. It was our custom to repeat the test after each serum injection, although most of our serum was given as a large single dose one hour after the test dose.

If an urticaria-like wheal appears at the site of injection within twenty minutes, and especially if pseudopods form and the circumference of the wheal extends, the reaction is considered positive. A flare often accompanies the wheal formation but is not to be used as an index of positivity unless the control reaction is absolutely negative. It can be seen from the tables that the result is rarely positive until after serum has been given. Occasionally from five to eight days after onset, at or near the spontaneous crisis, the reaction becomes positive, indicating the presence of sufficient antibodies. Although not all patients have sufficient excess of antibodies to produce a positive result at the time of normal crisis, the majority will show it a day or so before or after normal crisis.

The test is repeated within three hours after the last serum has been given, and if the reaction is positive in the uncomplicated cases no more serum is needed. In the presence of complications such as bacteremia, more serum is needed even though the result is positive. A good rule to follow is to give more serum if there is doubt as to whether the reaction is positive or negative. An unequivocally positive reaction is always obtained after sufficient serum has been given, the only possible exception occurring when a patient is dying and has lost the reactivity of the skin.

Sterile stock solutions of the various capsular carbohydrates in 1:1,000 concentration in physiologic solution of sodium chloride keep indefinitely. For hospital use the 1:10,000 dilution keeps well at 40 to 60 C. all year, and from this dilution 0.1 cc. may be taken into a tuberculin syringe in order to inject 0.05 cc. intracutaneously. A similar amount of sterile physiologic solution of sodium chloride is injected as a control.

Scheme of Dosage.—Since few patients with fully developed pneumonia require less than 60,000 units of antiserum, this amount or more may be given as an initial dose, after which the absence of a positive reaction to the intracutaneous polysaccharide test is an indication for giving additional doses of 20,000 to 40,000 units at two hour intervals until the reaction becomes positive. Thus this test enables one in a sense to titrate with antibody, the type specific capsular carbohydrate being the indicator and a positive skin reaction denoting the end point.

It is difficult to establish clinically the point at which adequate serum has been given. A fall in the patient's temperature is an uncertain index, as it may follow temporarily the administration of any serum or foreign protein. If one waits for a secondary rise in temperature valuable time is lost, and a one or two day pneumonia may be converted into a two or three day disease with the attendant statistical increase in mortality.

With the use of the skin test, the delay between the first and the second dose is a matter of only two or three hours. Frequently the reaction becomes positive while the first dose of serum is being given, thus enabling one to save the unopened vials containing the

balance of the clinically estimated dose. In this way the test obviates the necessity for overtreatment. It has been customary in the past to overtreat as the lesser of two evils. In fact an amount in excess of the clinically calculated dose was formerly given in order to be safe. Overdosage offers no clinical advantage and subjects the patient to needless expense. Since the saving effected by the use of this test in our series amounted with but few exceptions to 20,000 to 100,000 units per

† The only one of the five who died that had a positive test before serum.

patient, it is apparent that where serum is supplied to indigent patients by the state the use of the test has immense economic value.

In the presence of complications such as empyema, the temperature, pulse and respiration are no longer valued criteria of adequate therapy. Clinically the patient appears to need more serum, and frequently the presence of empyema may not be suspected. A positive skin reaction in such an instance indicates that the patient can be benefited not by additional specific therapy but only by procedures which will remove the focus of infection.

The presence of a positive skin reaction in the absence of clinical improvement after serum has been given may be the first sign of incipient pus or bacteremia.

It must be emphasized that in the rare cases, perhaps with bacteremia or endocarditis, the reaction may be negative even though type specific antibody is demonstrable in the blood and when the infection may be advancing. In such cases the skin test cannot be used as a criterion for serum dosage.

RESULTS

From table 1 it can be seen that of a total of 114 patients with pneumonia 110 had negative reactions to the polysaccharide skin test before serum therapy. Of these, 105 showed a positive reaction after serum. Of the four patients who showed a negative result after serum, three subsequently died although they received more than enough serum (300,000 to 400,000 units) to cause a strongly positive skin reaction in the average patient with the same number of lobes involved.

Duration of Positive Reactivity to Skin Test.—In the few cases in which there was a history of hives, it was noted that the control with physiologic solution of sodium chloride did not cause a reaction. When skin tests were performed during the days of serum sickness, the results were in no instance interpreted as positive unless they were also positive after the recovery from serum disease.

From table 3 one can see that the patients who recovered displayed great variability in the duration of positive reactivity to the skin test after serum therapy. The duration did not vary directly with the dosage of serum or with the period from onset of the disease to the time serum was given. If, however, serum is given late in the course, the concentration of antibodies supplied by the patient himself may be increasing. The average duration was about ten days after serum was given. There seemed to be no relation between length of the positive phase of the polysaccharide test and serum sickness. The patients with complications tended to have a longer phase of reactivity than did those without complications.

Type I Pneumonia.—Of the fifty-two patients tested before and several times after serum therapy, only two had a positive result before serum was given. Of those with a negative result before serum all but one reacted positively after serum. This patient was given 60,000 units in the thirty-sixth hour of his pneumonia. The injection was followed within twenty-four hours by a crisis but without appearance of a positive reaction. Of the two patients who died, one had a positive reaction before serum therapy on the fifth day of disease and the blood culture became sterile after the total of 360,000 units had been given. Death occurred nine days later. At autopsy, consolidation of the entire right lung with an acute aortic endocarditis was demonstrated. The other patient's reaction remained negative before and after serum in the presence of fatal bacteremia.

Type II Pneumonia.—Fourteen patients were tested and all showed a negative reaction before and a positive reaction after serum was given. The only patient who died was admitted eight days after onset, was delirious and had bacteremia. Although patients with bacteremia late in the disease usually have sufficient antibodies to produce a positive reaction before serum is given, this patient did not, which of itself may be a bad prognostic sign. Blood taken before and twice after serum was given failed to show any agglutination with type II smooth organisms and only slight aggluti-

nation to a rough type II strain after serum was given. The result of the polysaccharide test was also negative. Large amounts of serum may fail to cause a positive reaction in such cases. Lack of tissue or skin reactivity may be a factor when antibodies are present but the result of the skin test is negative.

Type V Pneumonia.—Twelve of thirteen patients had a negative reaction before serum was given. One of the two patients who died, who had a positive reaction before serum therapy on admission, three weeks after onset of the disease, had bacteremia with empyema. In spite of a normal temperature for three days and a negative blood culture after being given 300,000 units

of type V serum, he died on the ninth hospital day. Autopsy revealed an acute pneumococcus aortic vegetation. The other patient who died had negative reactions both before and after treatment with 340,000 units of serum. Bacteremia disappeared with seeming clinical improvement for several days. On the ninth hospital day death suddenly occurred from circulatory failure.

Type VII Pneumonia.—All fourteen patients had negative reactions before and all had positive reactions after serum therapy, with recovery.

Type VIII Pneumonia.—Of nineteen patients, eighteen had negative reactions and one a positive reaction before administration of serum.

Type XIV Pneumonia.—Two patients had negative reactions before and positive reactions after serum was given. Both recovered.

Pneumonia of Types III, IV and VI.—Several patients were tested at intervals and after the crisis, which occurred either spontaneously or with the aid

VIII skin test was positive. The next day it was 3 plus; it became negative one week later. The patient recovered uneventfully.

J. B., aged 72 years, the husband of M. B., was admitted four days after his wife on the second day of his disease, which partially involved the right upper lobe, beginning at the hilus. This was also due to the type VIII pneumococcus. The temperature was 102.6 F., pulse rate 115 and respiratory rate 26. The type VIII polysaccharide test did not produce positive results until after 100,000 units of serum had been given. Crisis occurred within twelve hours. The reactions remained positive for the duration of the hospital stay of ten days.

V. P., aged 28 years, was admitted on the eighth day of type II pneumonia and had 100,000 units of type II serum; the reaction did not become positive until another 40,000 units had been given. Crisis occurred in twenty-four hours and recovery ensued. In this case one would have estimated that an additional 40,000 units, at least, was necessary.

L. C., aged 21 years, was given 100,000 units of type I serum on the fourth day of pneumonia of type I in the left lower lobe. The polysaccharide test produced a negative reaction before and a positive reaction one hour after the serum therapy. In twelve hours, however, the reaction was negative although the temperature was normal. Subsequent tests gave negative results for the next seven days, after which the reaction became positive again, on the eleventh day from onset of the pneumonia, remaining positive for the next three days of the hospital stay. More serum was not given when the reaction became negative because clinically the patient was well on the road to recovery, with normal temperature and respirations and with but slight elevation of pulse rate. Had the temperature become elevated above 101 F. (rectal) with a negative reaction, in the absence of other causes for the temperature, more serum would have been indicated.

If the temperature remains elevated, the reaction positive and the disease unaffected by the usual amount of serum, the sputum should be retyped. Thus it is best to combine clinical judgment with all tests. Apparently enough serum was given to control the infection but not enough to diffuse into the skin and react with the polysaccharide. If bacteremia had been present, more serum would have been indicated as soon as this was determined, in spite of a positive or negative reaction to the skin test with type specific polysaccharide.

PNEUMONIA OF MORE THAN ONE TYPE

That the polysaccharide test is of value in the differential treatment of pneumonia due to more than one type is shown by the following cases:

A 26 year old woman entered on the second day after onset of pneumonia with a chill, cough and rusty sputum. Types III and VIII pneumococcus were directly found in the sputum by the modified Neufeld technic. Early consolidation of the right lower lobe was present. Since the type VIII organisms were present in greater number per oil immersion field than the type III, 80,000 units of type VIII serum was given and crisis occurred in twelve hours. The reaction was negative for types III and VIII before and positive for type VIII after serum therapy.

A patient with type I pneumococcal pneumonia, recovering spontaneously, was admitted on the tenth day with a temperature of 104 F. after two days of normal temperature. Careful physical and roentgenographic examination revealed a parenchymal process in the right middle lobe. The original process had been in the left lower lobe. A skin test with type I polysaccharide yielded unequivocally positive results, showing the presence of a homologous antibody and reactive dermis. The presence of empyema was not suggested by physical and roentgenographic signs. No sputum was available, whereupon a lung puncture was performed; type VIII pneumococcus was isolated directly from the new area of involvement. There was prompt defervescence following the administration of type VIII anti-pneumococcus serum; on recovery the patient reacted to both type I and type VIII polysaccharides.

TABLE 3.—Duration of Positive Skin Test*

* In thirty-four of the thirty-five cases reactions were negative before serum was given.

of sulfapyridine. In general, the patients treated with sulfapyridine had a negative reaction before the fifth day of the pneumonia, even those whose temperature fell on the first or second day. Very few had a positive reaction after the sixth to tenth day from the onset of the pneumonia, the time at which antibodies naturally occur in high concentration. Of the few patients seen at the time of spontaneous crisis, several had positive reactions to the polysaccharide test and recovered without specific therapy.

PNEUMONIA OF A SINGLE TYPE

A 21 year old man was admitted on the third day of type I pneumonia with a rectal temperature of 104 F., pulse rate of 100 and respiratory rate of 32 per minute. Slight cyanosis and delirium were present. The lower lobe of the right lung was consolidated. Clinically, it was estimated that at least 140,000 units of serum would be necessary and we prepared to give 160,000 units. The type I polysaccharide test, however, produced a positive reaction by the time 100,000 units of serum had been given. Crisis followed in twelve hours. Several such instances could be cited of patients in the older age group.

M. B., aged 70 years, was admitted on the seventh day of type VIII pneumonia with a temperature of 103 F., pulse rate of 100 and respiratory rate of 24. There were no signs of approaching crisis. The white cell count was 30,400, with a marked shift of segmented leukocytes. Consolidation of the right middle lobe was evidenced by physical signs and a roentgenogram. Types I and VIII polysaccharide skin tests yielded negative results. Eighty thousand units of type VIII serum caused a crisis in sixteen hours, and the reaction to the type

T. H. had a typical onset with chills and rusty sputum three days before entry. Type VII pneumococcus was isolated directly from the sputum and 100,000 units of type VII horse serum was given. Two days later the temperature was still elevated, being 104.6 F., the pulse rate was 122 and the respiratory rate 32. Since the reaction to the type VII polysaccharide test was positive we were assured that enough serum had been given. No evidence of empyema or bacteremia was found. Accordingly the sputum was retyped, and this time type I pneumococcus was found in abundance with a few type VII organisms. Type I skin test was negative and 160,000 units of the homologous serum was given before the skin reaction became positive for type I, this being the fifth day of the disease. Within twenty-four hours the temperature was normal. Reaction to the type VII polysaccharide test became negative eleven days after serum was given, when the reaction to the type I test was still positive. Recovery was uneventful.

In seven instances of pneumonia with more than one type of pneumococcus in the sputum, the skin test enabled us to know that adequate amounts of serum had been given for one of the types in each case and that serum was the logical cause of the crisis which occurred within at least forty-eight hours and before the seventh day of the disease. In two of these cases, lung puncture was done to determine the actual cause of the pneumonia, which proved to be pneumococcus of the same type as that for which serum was given. This was necessary when the multiple types in sputum were of the more common variety. Sulfapyridine can also be used to advantage in such cases.

FOUR SPECIAL CASES

All patients were treated without selection as soon as the organism could be typed. Four patients who were moribund on admission were treated with serum in order to determine what little benefit might accrue. In all but one of these cases, which will be described, the type specific polysaccharide test was found to give negative results before and after therapy with large amounts of serum. It appears that in the presence of terminal shock the skin is no longer reactive. The reaction was positive before and after serum administration in one moribund patient admitted twenty-one days after onset of type V pneumonia involving the entire left lung, with an encapsulated empyema and type V pneumococcus in the blood culture. The blood culture was sterile after 300,000 units of serum had been given. The temperature was almost normal for three days after serum therapy, but the patient died on the ninth hospital day. Sulfapyridine was given the day after the second rise in temperature and continued for five days. Aortic valvular pneumococcal endocarditis was seen at autopsy in addition to the lesions described. The other three patients died within twelve hours of admission but none of them had a serum reaction. There were no great variations in blood pressure and pulse.

SUMMARY

In 114 cases of lobar pneumonia caused by type I, II, V, VII, VIII or XIV pneumococcus, type specific antipneumococcus rabbit serum was used. The reaction of the patient to intracutaneous tests with the type specific polysaccharide from the capsule of a homologous type of pneumococcus was determined before, during and after the administration of the serum.

One hundred and ten of the patients had a negative reaction to the test, indicating a low content of circulating antibody, before serum was given. The test proved to be a valuable aid in the more accurate esti-

mation and control of the optimum dose of serum necessary for the successful treatment of the patient.

In thirty-five cases, daily skin tests with the polysaccharide were performed until the patient was discharged from the hospital. In twelve of these cases the reaction became negative before the patients were discharged (seven to nine days), and in twenty-three it remained positive (nine to nineteen days).

In some cases without complications, a positive reaction to the skin test at the time of admission on the sixth or seventh day of the pneumonia enabled us to withhold treatment with the assurance of the presence of sufficient antibodies to cause a crisis with favorable outcome. Not all patients with spontaneous crises, however, have the excess of free antibodies necessary to cause a positive reaction to the test. Some patients with myocardial damage or cardiac decompensation need serum even though they show a positive reaction.

A persistently negative skin reaction appears to have some value from a prognostic standpoint. In most cases in which a positive reaction did not occur after the administration of large amounts of serum the disease terminated fatally. In such cases the blood agglutinins were often found in high titer. A skin formerly reactive to polysaccharide may lose its reactivity, even in the presence of free circulating antibody, when the patient is moribund. A positive reaction in a patient with bacteremia does not mean that no more serum is needed. Dermal injection of pneumococcus polysaccharides into human beings may induce subsequent reactivity of the dermal cells, and this fact is to be borne in mind in studies of skin sensitivity when repeated intradermal injections of these agents are involved.¹⁰

The polysaccharide skin test is a valuable, though not infallible, means of measuring the serum required for treatment in a given case of pneumococcal pneumonia.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, SECRETARY.

AUGUSTANA MODEL SAFETY GAS OXYGEN APPARATUS ACCEPTABLE

Manufacturer: Safety Gas Machine Company, 1163 Sedgwick Street, Chicago.

This unit is designed for the administration of inhalation anesthesia. It utilizes D cylinders of oxygen, carbon dioxide, nitrous oxide and ethylene, with provision conveniently made for one extra tank of each gas to be attached to the apparatus. In addition, there is an extra yoke provided for the administration of cyclopropane. To each of the sets of yokes (except those for cyclopropane) to which the cylinders are connected is attached a competent reducing valve. The cyclopropane yoke has a pressure gage attached with which the operator may estimate the amount of gas remaining in the cylinder. The units are so designed that different gases cannot leak from one cylinder to another unless the cylinders are connected to the machine in a way other than specified.

There is a central mixing chamber into which gases may be admitted for delivery either singly or in various combinations. A gas is admitted to the mixing chamber through a visible sight-feed in an individual water manometer. All manometers displace against a common head of water. The flow of each gas may be regulated by individual needle valves; thus any desired proportions within reasonable limits may be obtained. There is a by-pass valve as a quick source of supply for oxygen. The manometers are apparently each graduated in gallons per hour.

There is an ether vaporizer attached, which permits the addition of ether vapor to the delivered gas mixture. It is so arranged that the gases may be passed in varying proportions through the ether container by regulation of the valve.

The remainder of the apparatus consists of a typical so-called "circle filter" carbon dioxide absorption unit. The canister containing the soda lime may be shut off from the circuit at will.

An exhalation valve enables the operator to utilize the so-called "open," "semiopen," or "semiclosed" technics of anesthetic administration. The valves are apparently of a rubber fabric material. The rubber tubing and breathing bag appear to be durable. The size of the bags, type of face masks and soda lime mesh are optional.

The apparatus is supported adequately on a pedestal equipped with rubber-tired casters. Even though somewhat large, it is easily wheeled about.

The unit was submitted to a qualified physician, who studied its therapeutic efficiency and applicability. The following was concluded from his report:

There is some resistance to respiration, as in all types of so-called "circle-filter" anesthetic apparatus. This is of the order of 2 to 4 cm. of water with ordinary breathing. While this resistance is of little import in a healthy subject, in the case of a debilitated patient undergoing a long operation it is sometimes of considerable importance. It is common to all models of this type of apparatus of all manufacturers.

When the carbon dioxide absorber is in the breathing circuit, it efficiently removes carbon dioxide. This was proved by actual chemical gas analysis. It was found that 4-8 mesh soda lime produced somewhat less resistance than an 8-14 mesh to breathing and was just as efficient in its removal of carbon dioxide.

A comparatively small breathing bag allows for more flexibility, in that anesthetic mixtures can be changed more rapidly and smaller quantities of gas or vapor are necessary.

The investigators commented that they saw no serious objections to the use of this apparatus. They qualified this statement to this extent: Any skilled anesthetist can give good anesthesia with any piece of apparatus within certain limits. In the last analysis, it is the anesthetist rather than the apparatus that gives the anesthesia.

The Council makes no comment expressed or implied regarding any explosion hazard. It is extremely difficult to determine conditions for such safety.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Augustana Model Safety Gas-Oxygen Apparatus for inclusion in the Council's list of accepted devices.

DUAL-SPECTRUM ULTRAVIOLET LAMP, MODEL 300, ACCEPTABLE

Manufacturer: Bristow and Company, 2831 West Pico Boulevard, Los Angeles.

The Dual-Spectrum Ultraviolet Lamp, Model 300, is a therapeutic lamp designed exclusively for the use of the physician. Evidence was provided to show that 82 per cent of the radiation is between 2,000 and 2,600 angstroms, 16 per cent between 2,600 and 3,000 angstroms and 2 per cent between 3,000 and 3,200 angstroms. The firm claims that, by the use of special glass tubing in addition to quartz tubing, approximately 50 per cent more energy is provided between the bands 2,600 and 3,000 angstroms than is customary with quartz construction.

The lamp consists of a base containing three transformers; a tubular stand supporting the lamp, a time clock, cable attachment, switches and an official unit (Council accepted August 1938); and a reflector containing the burner. The weight of the unit is 47 pounds, the outside diameter of the reflector is 36 cm., and the supporting column is adjustable to different heights. An air cushion in the column serves as a shock absorber. The reflector is adjustable horizontally and vertically and may be rotated in both axes.

The reflector, with a bakelite back and an aluminum shell, supports two types of tubing in the burner. One is of quartz and another of a special composition glass which is coiled side by side with the quartz tubing in a flat hexagonal pattern. These tubes contain mercury and a mixture of inert gases and are energized by two transformers made for 50 to 60 cycle current, with 115 volts on the primary and 1,800 volts on the secondary at 90 M.A. Together they consume 180 watts. The official transformer has the same specifications on the primary side with 2,000 volts on the secondary at 9 M.A.

The firm submitted evidence regarding the radiation (including two spectrograms), power consumption and other physical data. The lamp was reported to produce the intensity of ultraviolet light in microwatts per square centimeter shown in table 1.

TABLE 1.—Intensity of Ultraviolet

	Quartz Light	Special Glass	Both
At 4 inches.....	5,300	2,300	6,200
At 24 inches.....	510	320	640

According to the report of physiologic tests carried out on abdominal untanned skin at 24 inch spacing, the erythema time on this lamp is as given in table 2.

TABLE 2.—Calculated Minimum Perceptible Erythema Time

	Seconds
Quartz light	75
Special glass light.....	105
Both	52

The lamp was examined by the Council, and the claims were found to be acceptable from a physical standpoint, and the lamp was determined to be adequate for clinical service.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Dual-Spectrum Ultraviolet Lamp, Model 300, for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

AZOCHLORAMID (See New and Nonofficial Remedies, 1939, p. 256).

The following dosage form has been accepted:

Azochloramid Saline Mixture Tablets, 8.5 grains (for preparing 2 ounces of a 1:3,300 aqueous solution): Each tablet contains azochloramid 0.28 grain, sodium chloride 7.60 grains, disodium phosphate 0.54 grain and monopotassium phosphate 0.08 grain.

BACTERIAL VACCINE MADE FROM THE TYPHOID BACILLUS AND THE PARATYPHOID "A" AND "B" BACILLI (See New and Nonofficial Remedies, 1939, p. 443).

The Gilliland Laboratories, Inc., Marietta, Pa.

Typhoid-Paratyphoid Bacterial Vaccine Immunizing.—Also marketed in 50 cc. vials, twenty immunizing doses containing in each cubic centimeter 1,000 million killed typhoid bacilli, 500 million killed paratyphoid A bacilli and 500 million killed paratyphoid B bacilli.

ANTIMENINGOCOCCIC SERUM (See New and Nonofficial Remedies, 1939, p. 403).

The National Drug Company, Philadelphia.

Antimeningococcic Serum, Refined and Concentrated.—In packages of two 10 cc. double-end ampule-vials with intraspinal and intravenous needles; in package with intravenous needle and one 10 cc. double-end ampule-vial with gravity outfit and intraspinal needle; and in packages of one 20 cc. ampule-vial, with outfit (hospital package). A 1 cc. vial of 1:10 dilution of the specific serum is included with each package to determine the sensitivity of the patient.

EVOLUTION OF OUR KNOWLEDGE OF TUBERCULOSIS

Subtle, evasive, paradoxical, intricate and complex are terms that apply to the microscopic parasite which a recent writer¹ characterizes as "A Bug Full of Tricks." The early history of devastation wrought by this armored enemy of mankind is still preserved in the distorted joints and spinal columns of prehistoric skeletons and Egyptian mummies. The recent history is accumulating much faster than is the record of many other parasites that revolve about the microscopic or chemical and immunologic analysis.

The code of Hammurabi, written at least 2,000 years B. C., indicates some knowledge then of tuberculosis. Greek writers described the clinical features of tuberculous disease in the fifth century B. C. In the second century Arctaeus not only accurately described the clinical features but suggested routine treatment. In spite of their keen observations, Hippocrates and Galen recognized the hopelessness of a problem that appeared entirely occult. Galen probably never suspected that his own illness was a manifestation of phthisis, for bizarre beliefs befogged the issue. Fracastorius in 1546 expressed the belief that phthisis was due to invisible germs. Paracelsus in 1567 wrote about miners' phthisis. Franciscus Sylvius in 1650 suggested the connection between scrofula and phthisis and that tubercles precede phthisis. The first postmortem report of miliary tuberculosis was given by Manget in 1700, about which time Morgagni refused to perform necropsies on the victims of phthisis because of his fear of contagion.

The tuberculosis death rate reached its highest point about the middle of the eighteenth century, coincident with rapidly increasing facilities for the acquisition of knowledge. Auenbrugger made an epochal contribution in describing immediate percussion in 1761. Late in the eighteenth century Whytt described tuberculous meningitis, and Pott tuberculous destruction of the

spine. In 1816 Petit described laryngeal tuberculosis, and Portal suggested a connection between consumption and engorgement of lymphatics. It is said that William Stark, who was studying the pathology of phthisis in London under the renowned John Hunter, died of tuberculosis as the result of a wound received in the morgue. Baillie, the successor of Stark, also developed an infection of the hand after performing a necropsy and died of tuberculosis, but not until his years of study had clarified the knowledge of the tubercle.

At the turn of the nineteenth century Willan discussed the relation of erythema nodosum to tuberculosis. Bichat advanced from the organ pathology of Morgagni to tissue pathology within the organ. Bayle presented in his volume "Pulmonary Phthisis" clinical observations checked by more than 900 necropsies. Corvisart popularized percussion early in the nineteenth century. Later Piorry's method of percussion and Laënnec's new method of auscultation had a profound influence on the progress of physical diagnosis. Laënnec appropriated all previous scientific advances and with remarkable genius drew up a minute history of nearly 400 cases of phthisis before he was 22 years of age. He recorded virtually all that is now taught about the physical diagnosis of diseases of the thorax. He published in 1918 nearly 800 pages on auscultation and diseases of the chest. The advances of the nineteenth century would not have developed so rapidly without the invention of the stethoscope by Laënnec, who himself died of pulmonary tuberculosis. Contemporary with Laënnec, the great clinician Louis, who also suffered from tuberculosis, correlated the symptoms and pathology in the light of the necropsy, and through his teachings and pupils—Oliver Wendell Holmes, George C. Shattuck, William Pepper, Gerhard, Stille, Power, Swett and Clark—he was largely responsible for the establishment of clinical medicine, with special interest in physical examination, throughout the world. Virchow, contemporary with Louis, advanced from tissue pathology to cellular pathology and joined the dualist Schönlein, who coined the word "tuberculosis." At the University of Vienna, Skoda's (1805-1881) skill in diagnosis by means of percussion and auscultation led to the establishment of a special department on chest diseases to which students came from all parts of the world. Skoda's work was brilliantly complemented by his great contemporary Rokitansky, who is said to have performed more than 30,000 postmortem examinations.

A great scientific awakening was imminent by the middle of the nineteenth century. Villemin demonstrated in 1865 in a series of masterly experiments the specific nature of tuberculosis by means of inoculation. Gerlach in 1870 proved that milk from tuberculous cows may convey the disease. Medicine began to move into a new era, which was to see

1. Moorman, Lewis J.: A Bug Full of Tricks, J. Oklahoma M. A. 32:204 (June) 1939.

the development of modern laboratory methods. The tubercle bacillus was seemingly preparing a way for its own discovery and for the surrender of many of the secrets of its occult powers. The first pathologic laboratory was established by Virchow in Berlin in 1856 and the first hygienic laboratory by Pettenkofer in 1878. In 1882 Koch discovered the tubercle bacillus. Just before Koch's discovery Trudeau, Dettweiler and others became pioneers in the sanatorium management of patients, and in a short while artificial pneumothorax, another revolutionary method of treatment, was to be introduced by Forlanini.

Four thousand years has been surveyed for this brief statement of evolution of knowledge of this disease. Still from year to year more and more is being written. As the unsolved problems related to the tubercle bacillus remain infinite, so tuberculosis remains the greatest killer of man during the most useful period of his life.

POSTSCARLATINAL NEPHRITIS

Some years ago Burky¹ announced a discovery which many immunologists credited with opening up "so many new broad and inviting possibilities that it is fairly bewildering."² He found that lens proteins are nonantigenic when injected into homologous animal species. If the lens substance is mixed with staphylococcus filtrate, however, its latent antigenicity is in some way activated or supplemented, so that it becomes an effective sensitizing or immunizing agent. Rabbits injected with toxin "synergized" or "potentiated" lens protein not only develop antilens precipitins of high titer (e.g. 1:50,000) but also develop degenerative lesions in their own crystalline lens. These lesions duplicate the picture found in human cases of endophthalmitis phaco-anaphylactica. Extending his work to other tissue products, Burky found that in rabbits high titer antibodies could be produced by combining staphylococcus toxin with homologous muscle proteins.

Since the publication of Burky's discovery, many attempts have been made to apply his synergic technic to the production of improved vaccines and antisera. A few attempts have been made to apply it to the etiology of senescence or degenerative disease. The latest is its application to the etiology of post scarlatinal nephritis.

Lindemann³ showed that a condition closely simulating glomerular nephritis can be produced in laboratory animals by intravenous injection of heterologous anti-kidney serum. Animals injected with such cytotoxic serums develop albuminuria, hematuria, cylindruria, oliguria and occasionally anuria. In all these tests, however, the nephrotoxic serum was produced in a foreign animal species. All attempts to develop a nephrotoxic serum by injecting rabbits with homologous kidney

material have thus far been unsuccessful. Kidney proteins, apparently, are nonantigenic in the body of the animal of origin.

Applying the Burky technic, however, Schwentker and Comploier,⁴ of the Baltimore City Health Department, injected rabbits with rabbit kidney emulsions plus streptococcus or staphylococcus toxin. High titer nephrotoxic serums were produced by both technics. Specific absorption tests showed that the antisera thus produced contain at least two nephrotoxic antibodies. First there was a relatively high titer complement deviating antibody, specific for kidney parenchyma. This is accompanied by a relatively low titer antibody, which reacts with both kidney and brain emulsions. This second antibody is interpreted by the Baltimore clinicians as presumably specific for the connective tissue elements common to brain and kidney.

Having shown that toxin reinforced emulsions of homologous kidney are antigenic in rabbits, the Baltimore clinicians attempted to determine whether or not specific nephrotoxic antibodies are developed in the human body during the course of streptococcal infections. Complement fixation tests were therefore made with the sera of forty patients in various stages of scarlet fever, with twenty-nine control tests on patients without any sign of streptococcal infection. Thirty-seven (92 per cent) of the scarlet fever patients gave positive nephrotoxic serum reactions, as contrasted with but three (10 per cent) of the control patients. These results indicate that most persons suffering from scarlet fever develop circulating antibodies against their own kidney tissues, a reaction rarely seen in normal persons and then presumably due to unrecognized staphylococcal or streptococcal infection.

From these data Schwentker and Comploier conclude that streptococcus toxin damages some of the kidney tissue during the primary infection in scarlet fever. This damage may be clinically insignificant. The denatured kidney proteins thus formed, however, are released, "activated" or "potentiated" to "complete" antigens, stimulating the production of antibodies specific for kidney tissue. These antibodies may be of sufficiently high titer to give rise to acute hemorrhagic nephritis. A similar immunologic vicious circle had been previously proposed by Schwentker⁵ to explain the etiology of postinfectious encephalomyelitis. The clinical and pathologic picture of encephalomyelitis is readily produced in monkeys by repeated injections with partially denatured brain emulsions. If the Schwentker theory of the etiology of postscarlatinal nephritis is confirmed, the development of a logical method of interrupting or preventing the nephrotoxic immunologic vicious circle should not be beyond ingenuity.

COMBINED (ACTIVE-PASSIVE) DIPHTHERIA PROPHYLAXIS

Fifteen years ago Ramon and Lafaille¹ suggested a new method of prophylaxis against diphtheria. By this improved method the transient passive immunity caused by injecting antitoxic serum is supplemented by a semi-permanent active immunity caused by the simultaneous injection of diphtheria toxoid. A number of European investigators confirmed the theoretical possibility of such combined immunization in laboratory animals. Gundel and König,² for example, found that by a proper selection of dosage and type of antiserum and of toxoid a relatively permanent active immunity could be superimposed on the transient passive immunity in rabbits. This combined immunity was sufficient to protect laboratory animals from diphtheria toxin over a long period. The only question undetermined by their work was whether or not a similar duplex immunization was possible or feasible in man.

Now the clinical feasibility of this combined technic is denied by Paschla³ and by Frey and Schmid,⁴ of the Red Cross Hospital, Vienna. They injected 2,000 units of antidiphtheritic horse serum, cow serum or sheep serum intramuscularly into each of twenty children, followed by single or multiple subcutaneous injection with diphtheria toxoid. Alum toxoid was used in most of the tests. The degree of combined active-passive immunity was estimated in these children by periodic titrations of the blood serum.

As a typical example of their data, the antitoxin titer rose to 1.75 units per cubic centimeter of the patient's blood by the third day after the duplex injection. This titer then fell to 0.4, 0.2 and 0.1 unit respectively by the end of seven, fourteen and twenty-one days. On the twenty-eighth day only a trace of the passively transferred antitoxin was detectable, which trace completely disappeared by the forty-fifth day. Active immunity was not demonstrable. Control patients injected with toxoid alone developed relatively high antitoxic titers.

Under the conditions of their test, therefore, the toxoid was not only an ineffective immunizing agent but apparently had the deleterious effect of hastening the elimination or destruction of the transferred antitoxin. Their general conclusion is that combined active-passive immunization is not feasible in human medicine, the two types of immunization being incompatible with each other. This conclusion was dramatically confirmed by one of their patients, who contracted diphtheria during the course of their attempted duplex immunization. Whether or not a combined active-passive immunity is possible or feasible in specific infections other than diphtheria was not tested by the Austrian clinicians.

Current Comment

THE CHRISTMAS SEAL

Two hundred thousand persons are alive in the United States today who would have been dead of tuberculosis if last year had been 1904. Since that year, which marked the inception of the National Tuberculosis Association, the mortality rate from this disease has been cut down from 201 deaths per hundred thousand of population to 49 in 1938. People are now being urged to buy Christmas Seals, which help to finance the work of this association and its 2,500 affiliated organizations in all parts of the country. A part of the money derived from the sale of these seals goes into a fund which maintains a rehabilitation program for tuberculous persons in sanatoriums. But the real problem in fighting tuberculosis involves education: Those who have tuberculosis in its incipient stages can be cured if they are aware of their disease. In order to find these early cases, the people must be educated to look for it. In spite of the improvement of diagnostic methods, only 13 per cent of patients admitted to sanatoriums are found to be in the early stages of the disease, thus showing that there are far too many with unrecognized cases in the community infecting their families and neighbors. Only by finding every single case can the disease be eliminated. Early examination, skilful diagnosis and prompt treatment are the factors that make tuberculosis curable and preventable. Persons with questionable cases should be promptly examined.

TESTIMONIALS OF THE DEPARTED FOR VALENTINE'S MEAT JUICE

An early report of the Council on Pharmacy and Chemistry (1909) pointed out that Valentine's Meat Juice was being promoted with fallacious claims that it is highly nutritious and is valuable in the treatment of pneumonia, diphtheria and typhoid. Such claims are no longer made. Recently physicians have received a letter referring to an accompanying booklet containing the "experience of Physicians who have, themselves, suffered from Gastric and Intestinal troubles and found Valentine's Meat-Juice of much comfort and satisfaction." Of the testimonials (twenty-one in number) eleven were from abroad. Of those supposed to have been given in the United States, it is interesting to note the following testimony of Dr. C.:

"Having had a very long and exhausting attack of Typhoid Fever, lasting from June until the following December, VALENTINE'S MEAT-JUICE was the only article of nourishment I could take and the only one I required. Yet long before my illness I had prescribed it in my practice in every variety of medical and surgical diseases coming under the care of a busy practitioner. I have never yet met with a case from Infantine life to Old Age that VALENTINE'S MEAT JUICE could not be given with the greatest advantage."

According to the records of the A. M. A. Directory, Dr. C. died ten years ago. The next testimony by a physician in America is Dr. M., who died in 1907. Dr. S. died in 1930. Dr. G., according to our records, graduated in 1885, but the American Medical Directory has lost all contact with him. Dr. K. died in 1929;

Dr. S. died in 1913; Dr. P. died in 1936. The American Medical Directory has no record of Dr. C. R. T. but it does have a record of Dr. E. R. T., in the same town, who died in 1919. Of Dr. T. L. P. it has no record; there is a doctor from the same town with a similar name who died in 1915. Dr. L. is not a member or Fellow of the American Medical Association but is apparently still living. In other words, only one doctor of the entire group of American physicians whose testimonials are offered by the Valentine's Meat Juice Company in the year 1939 is alive. The title of the booklet is "Report From Members of the Medical Profession Who Have Themselves Taken Valentine's Meat-Juice When Ill With Gastric or Intestinal Trouble." And now they are no longer ill; they are dead. But their testimonials linger on!

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Society News.—The Etowah County Medical Society was addressed in Gadsden recently by Drs. James O. Finney and Amos C. Gipson on "Complications of Peptic Ulcers" and "Immunization and Treatment of Acute Infectious Diseases" respectively. At a meeting of the Calhoun County Medical Society, Anniston, recently the speakers were Drs. James A. Ward on "Obesity Associated with Endocrine Disturbances" and Hugh M. C. Linder on "Empyema Thoracis with Special Reference to the Chronic Stage." Both are from Birmingham. Dr. John Ralph Morgan, Birmingham, discussed "The Treatment of Burns" before the Walker County Medical Society October 13 in Jasper.

ARIZONA

New Office for State Society.—The Arizona State Medical Association has opened offices at 202 Security Building, Phoenix, and employed Mrs. Kitty Ives Coleman as executive secretary. For the past three and a half years the association has had a part time assistant in a combined office with the Maricopa County Medical Society and library. The president of the association held a conference of presidents and secretaries of the county medical societies at Phoenix October 22 to discuss the program of the association for the current year.

ARKANSAS

Society News.—The Ouachita County Medical Society was addressed in Camden recently by Drs. James E. Knighton Jr. on "Some Problems in Cardiology"; James C. Willis Jr. and Willis J. Taylor, "Partial Gastrectomy," and Oscar O. Jones, "Treatment of Bursitis." All are from Shreveport.

University News.—The general offices of the University of Arkansas School of Medicine, Little Rock, were moved recently to the former home of the late Dr. Carle E. Bentley, which is adjacent to the school. This property was acquired through purchase several months ago, newspapers report. Space in the medical school occupied by offices since its construction will be converted into additional quarters for the library.

CALIFORNIA

Alumni Day.—The University of California Medical School will observe its alumni day November 24. The program will consist of clinics and fracture and medical ward rounds at San Francisco Hospital. During the operations, the preoperative and postoperative care and surgical methods will be discussed by a member of the staff. There will be also a program of entertainment, according to an announcement from the university.

DISTRICT OF COLUMBIA

Personal.—Robert E. Bondy, director of disaster relief of the American Red Cross, has been appointed director of public welfare of the District. Rear Admiral Perceval S. Rossiter, U. S. N., retired, formerly surgeon general of the navy, became September 19 chief of staff at Gallinger Hospital.

The Davidson Lecture.—Dr. Walter Freeman, professor of neurology at George Washington University School of Medicine, recently presented the Davidson Lecture before the Medical Society of the District of Columbia. His subject was "The Surgery of Mental Disorder." The lecture is given biennially and is named for Dr. Edward Young Davidson. The lecturer is chosen through essays submitted on a competitive basis.

Portrait of Dr. White.—A portrait of the late Dr. William Alanson White, for many years superintendent of St. Elizabeths Hospital and professor of psychiatry at George Washington University School of Medicine, was presented to the university in behalf of the medical faculty at the opening exercises of the school September 25. Dr. Charles S. White made the presentation and Mrs. Joshua Evans Jr. accepted it for the university in behalf of the board of trustees.

FLORIDA

Personal.—Dr. Luis Garcia will be director of a new tuberculosis hospital which was to be opened about October 10 on the site of the former Pine Health tuberculosis preventorium, Tampa newspapers reported. The hospital was made possible by the cooperation of the city and county with the aid of charitable organizations. Dr. Garcia has been in charge of the Tampa tuberculosis clinic since it was opened about two years ago. Dr. William McQueen, Sarasota, has been appointed superintendent of the Sarasota Hospital.

District Meetings.—The third annual meeting of the Southeast Medical District of the Florida Medical Association was held at West Palm Beach October 12, with headquarters at the Palm Beach Yacht Club. The speakers included Drs. Eugene C. Chamberlain, Fort Lauderdale, on "Isolated Myocarditis"; Hillard W. Willis, Miami, "Nephritis in Children"; George D. Lilly, Miami, "Surgical Treatment of Essential Hypertension," and Carlos A. P. Lamar, Miami, "Clinical Endocrinology of the Male, with Especial Reference to the Male Climacteric."—The North Central Medical District Society held its third annual meeting in Ocala October 26 at the Marion Hotel. Dr. Carl S. Lytle, Dunnellon, president of the Marion County Medical Society, gave the address of welcome. Among other speakers were Drs. Ralph E. Russell, Ocala, on "Hygiene of the Eyes"; Laurie J. Arnold Jr., Lake City, "Cervical Ribs"; Richard C. Cumming, Ocala, "A Young Doctor Looks at Socialized Medicine," and Walter E. Murphy, Raiford, syphilis.

ILLINOIS

Personal.—Dr. Otto L. Bettag, White Haven, Pa., has been appointed superintendent of the Livingston County Sanatorium, Pontiac, succeeding Dr. Julius B. Stokes, resigned.

Outbreak of Typhoid.—Twelve cases of typhoid with one death occurred at DePue, Bureau County, during September, according to the *Illinois Health Messenger*. The outbreak was ascribed to a raw milk supply used by all the patients. When the supply was cut off as a control measure the epidemic ended, the *Messenger* said.

Chicago

Dr. DeLee Observes Seventieth Birthday.—Dr. Joseph B. DeLee, professor emeritus of obstetrics and gynecology, the School of Medicine of the Division of Biological Sciences, University of Chicago, observed his seventieth birthday October 29 at a party planned to benefit the Chicago Maternity Center, which he founded. He was presented with cuff links forged from a pair of forceps which he used in his early days of practice. They were the gift of the staff of the center and were presented by Dr. Beatrice E. Tucker, who directs the institution.

IOWA

Obstetric Service in the Home.—A plan is under way to provide home obstetric service to indigent patients in Polk County. The program is to be financed by funds from the state department of health and cooperating groups are the state department of health, State University of Iowa College of Medicine, Polk County board of supervisors, the city health department, public health nursing association, Polk County Emergency Relief Administration, Broadlawns Hospital, the intern committee, the superintendents of the private hospitals

and the Polk County Medical Society. The objectives are to afford obstetric service in the homes of indigent patients; to enable the college of medicine to participate in such a service and use the opportunities for teaching; to afford an opportunity for interns connected with the various accredited Des Moines private hospitals to participate in the service and to reduce the number of obstetric patients in Broadlawns Hospital, making the beds available to the more complicated and serious types of cases in which hospitalization is imperative. The home service will operate through the outpatient department at Broadlawns and patients will be investigated and arrangements made by the social service department, according to the *Bulletin* of the Des Moines Academy of Medicine and the Polk County Medical Society.

KANSAS

Changes in Health Officers.—Dr. Cyril V. Black, Pratt, has been appointed health officer of Pratt, filling the unexpired term of the late Dr. Charles E. Phillips.—Dr. Edwin O. Squire has been appointed health officer for the Coffeyville board of health.

Library and Museum of Medical History.—Space has been provided in the Hixon Laboratory of the University of Kansas School of Medicine, Kansas City, for a new library and museum of medical history. Dr. Logan Clendening, who has been conducting a course in medical history at the university for many years, gave his collection of medical curiosities and his historical library as a nucleus for the new department. The building housing the laboratory was financed by the Hixon Foundation, the PWA and gifts from Mrs. Clendening, it was stated.

KENTUCKY

Poliomyelitis in Mountain Counties.—Fifty-five cases of poliomyelitis have been reported in Floyd County and additional cases in adjoining counties, newspapers reported November 2. Most of the cases were in rural areas. The state health department and the Kentucky Crippled Children's Commission are investigating the epidemic with a view to preventing spread of the disease and instituting treatment for those stricken. Ten cases were reported in Pike County, eight in Johnson and three in Lawrence.

LOUISIANA

Society News.—At the October meeting of the Tri-Parish Medical Association, comprised of the parishes of East and West Carroll, Tensas and Madison, Dr. William K. Purks, Vicksburg, Miss., spoke on allergy.—The Eighth District Medical Society was addressed in Alexandria October 11 by Drs. Conley H. Sanford, Memphis, Tenn., on "Kidney Diseases and Hypertension"; Donovan C. Browne, New Orleans, "Functional Colitis"; and Edwin J. Kepler, Rochester, Minn., "Obesity—An Endocrine Problem."

Postgraduate Instruction.—Members of the staff of Louisiana State University Medical Center, New Orleans, are cooperating in a series of postgraduate courses being given by the division of maternal welfare of the state board of health, the federal government and the state medical society. In October Drs. Rupert E. Arnell and William F. Guerriero, clinical professor of obstetrics and gynecology and instructor in obstetrics and gynecology respectively, gave postgraduate instruction to practicing physicians in northern Louisiana. Other members of the staff later will conduct similar courses in various subjects.

MASSACHUSETTS

Public Health Meeting.—The annual meeting of the Massachusetts Public Health Association was held in Boston October 26. The program was divided into sections with a symposium making up the board of health section; the speakers were Dr. John E. Gordon, Arthur D. Weston, C.E., and Sophie C. Nelson, R.N. In the laboratory section the speakers were Donald L. Augustine, Sc.D., on "Trichinosis"; William C. Boyd, Ph.D., "Uses of Blood Grouping"; and Dr. Frank E. Barton, Boston, "Use of Placental Blood for Transfusions." The child health section devoted its session to a discussion of "The Child: The Influence of Economic Factors."

Society News.—At a special meeting of the New England Heart Association in Boston October 30 Dr. Harry E. Ungerleider and Mr. James D. Ewing, Equitable Life Assurance Society, New York, discussed "Insurance Frauds and Disability Problems in Heart Disease."—The New England Pathological Society was addressed in Boston October 19 by Drs.

Lorne M. Gray, Toronto, Ont., "Fat Embolism"; Charles E. Dunlap, on "Effect of Radiation on the Blood" and Shields Warren, "Significance of Chronic Mastitis as a Precancerous Lesion."—Dr. Vincent Gerard Ryan, who holds a fellowship in the Austen Riggs Foundation under a grant from the John and Mary R. Markle Foundation, discussed certain aspects of cases falling in the neurotic-psychotic borderline before the medical advisory board of the foundation at its annual meeting in Stockbridge October 21. Dr. Austen Fox Riggs presided at the meeting. The paper was discussed by Drs. Adolf Meyer, Baltimore; Charles Macfie Campbell and Stanley Cobb, Boston; Earl D. Bond and Kenneth E. Appel, Philadelphia, and Arthur H. Ruggles, Providence, R. I., among others.

MICHIGAN

Society News.—Dr. Carl V. Weller, Ann Arbor, gave an address before the Ingham County Medical Society October 17 entitled "Shifting Points of View in Regard to Cancer."—Dr. Harold Henderson, Detroit, addressed the Jackson County Medical Society in Jackson October 17. His subject was "The Middle Aged Woman."—Dr. Francis Bruce Fralick, Ann Arbor, discussed "Ophthalmology and Its Relation to General Health" before the Kalamazoo Academy of Medicine, Kalamazoo, October 17.

Highland Park Physicians' Club.—The fourteenth annual clinic of the Highland Park Physicians' Club was held November 15 at the Highland Park General Hospital. The program opened with a clinical pathologic conference by Dr. Edgar H. Norris, professor of pathology, Wayne University College of Medicine, Detroit. Others on the program were:

Dr. Sumner L. S. Koch, Chicago, Infections of the Hand.
Dr. Edward J. Stieglitz, Garret Park, Md., Treatment of Hypertensive Disease from an Internist's Viewpoint.
Dr. Alfred W. Adson, Rochester, Minn., Treatment of Essential Hypertension by Extensive Sympathectomy.
Dr. Edward L. Cornell, Chicago, Analgesia and Anesthesia in Obstetrics.
Dr. Allen Graham, Cleveland, Diagnostic Criteria of Cancer.
Dr. Temple S. Fay, Philadelphia, Temperature Factors in Cancer and Embryonal Cell Growth.

Medical Service for the Low Income Group.—Michigan Medical Service, a nonprofit corporation for group medical care organized under special enabling legislation sponsored by the Michigan State Medical Society, is now ready to assist the low income group in Michigan to obtain the services of doctors of medicine in return for small monthly subscription payments. The plan will be administered by a board of directors consisting of from eleven to thirty-five representatives of the public and the medical profession. Local advisory committees will be established by the medical profession so that professional judgment will guide the relations with physicians concerning participation, fees and the rendering of services. According to the November state medical journal, the articles of incorporation of Michigan Medical Service have been certified by the attorney general and the necessary working capital has been advanced by the Michigan State Medical Society. The plan will go into effect in the near future and its operation will be under the direct supervision of the state insurance department. All employed persons under the age of 65 who can be enrolled in groups of twenty-five or more will be eligible for membership.

MINNESOTA

Study of Motor Accidents.—The Minnesota State Medical Association has appointed four physicians to conduct a study of motor vehicle accidents. Drs. Kano Ikeda, St. Paul; Maurice B. Visscher, Minneapolis; Dale D. Turnacli, Minneapolis, and Edward W. Ostergren, St. Paul.

Society News.—Included among the speakers before the Hennepin County Medical Society, Minneapolis, November 6, was Dr. Horace M. Korn, Iowa City, on "Arterial Hypotension."—The Scott-Carver Medical Society was addressed October 10 in Shakopee by Drs. Arthur C. Kerkhof and O. L. Norman Nelson, both of Minneapolis, on "New Aspects of Endoscopy" and "Problems of Pernicious Anemia" respectively.

Minnesota Medical Foundation.—The establishment of the Minnesota Medical Foundation at the University of Minnesota, Minneapolis, was announced at a dinner October 13 commemorating the fiftieth anniversary of the founding of the school of medicine. The foundation has been set up by alumni of the university to establish scholarships, professorships, lectureships, research and aid to worthy students. According to the *Minneapolis Tribune*, the foundation will have the power to receive gifts, endowments, the rights to patents, trusts and property to carry out its aims. Funds derived from these sources will be used exclusively to assist university authorities.

ties in improving and enlarging the scope of their activities in medicine. Dr. Erling S. Platou, Minneapolis, president of the Minnesota General Alumni Association, is chairman of the

MISSISSIPPI

Society News.—At a meeting of the Central Medical Society in Whitfield October 3 the speakers included Drs. Ellyson G. Meriwether on "Modern Psychiatry at the Descriptive Level"; Willard L. Waldron, "Psychosis with Pellagra; Preliminary Reports of Intraspinial Treatment with Synthetic Vitamin B₁"; Victor D. Thomas, "Differential Diagnosis Between Paranoid Condition and Dementia Praecox, Paranoid Type"; Clarence H. Denner, "Some Aspects of Metrazol Therapy," and Frank A. Donaldson and F. M. Clarke, Ph.D., "Fever Therapy in Central Nervous System Syphilis."

MISSOURI

Dr. Willard Allen Appointed to Washington University.—Dr. Willard M. Allen, assistant professor of obstetrics and gynecology, University of Rochester School of Medicine, Rochester, N. Y., has been appointed professor and chairman of the department of obstetrics and gynecology at Washington University School of Medicine, St. Louis. Dr. Allen graduated at Rochester in 1932. In 1935 he won the \$1,000 Eli Lilly Award of the American Chemical Society for distinguished research in biochemistry.

NEBRASKA

Postgraduate Course in Obstetrics and Pediatrics.—A postgraduate circuit course in obstetrics and pediatrics is being presented in five towns under the auspices of the committee on maternal and child health of the Nebraska State Medical Association and the division of maternal and child health of the state health department. The series began November 6 and will continue till December 2. The lecturers, who will conduct clinics during the day and give formal lectures at night, will be Drs. Morris Edward Davis, Chicago, the first two weeks, and Henry C. Hesselstine, Chicago, the last two. Dr. Harry A. Towsley, Ann Arbor, Mich., will be the guest pediatrician. The towns in which the courses are being held are Grand Island, McCook, North Platte, Scottsbluff and Chadron.

Society News.—Dr. Elliott P. Joslin, Boston, addressed the Lancaster County Medical Society, Lincoln, October 4 on diabetes. Drs. James Dewey Bigard and Frank Lowell Dunn, Omaha, addressed the Madison Six County Medical Society, Norfolk, recently on "Treatment of Nontuberculous Suppurative Diseases of the Chest" and "Treatment of Pneumonia" respectively. At a recent meeting of the Southwestern Nebraska Medical Society in McCook the speakers, all of Denver, were Drs. Edgar W. Barber on "Medical and Surgical Treatment of Goiter"; Wilfred W. Barber, "Sulfanilamide and Sulfapyridine," and Albert W. Metcalf, who showed color films on "Vascular Diseases of the Extremities."—Dr. Harry L. Alexander, St. Louis, discussed "The Newer Aspects of Allergy," before the Omaha-Douglas County Medical Society, October 10; Dr. Maurice C. Howard presented a case report on intractable asthma.

NEW YORK

Clinical Day in Buffalo.—The Buffalo Academy of Medicine held its annual clinical day November 8 at the Hotel Statler. The scientific speakers were Drs. Emil Novak, Baltimore, on "Rational Management of the Menopause"; Donald W. Gordon Murray, Toronto, "Heparin in Thrombosis"; Charles C. Higgins, Cleveland, "Prevention of Recurrent Renal Calculus" and Russell L. Haden, Cleveland, "The Problem of Osteoarthritis." Mr. Isaac F. Marcossou, New York, was the after-dinner speaker on "War and World Chaos."

County Society Offers Health Education Service.—The Medical Society of the County of Westchester has recently made available to parent-teacher groups, service clubs, women's clubs and other lay groups a new series of educational programs. The society will prepare each month a health talk, of which copies will be sent to organizations desiring them. In addition speakers will be available through the society's speakers' bureau for more extended discussions. The society also plans active solicitation of speaking dates for members who have volunteered to speak on a wide variety of health subjects. The entire program on health education will be offered as a public service without cost to the lay groups. Dr. Edward H. Marsh, White Plains, is chairman of the public health committee which arranged the new plan.

New York City

District Meeting.—The First District Branch of the Medical Society of the State of New York held its annual meeting at the Presbyterian Hospital October 11. There were clinics on general surgery, neurosurgery, obstetrics and gynecology, general medicine, pediatrics, ophthalmology, urology and radiotherapy. Among other features was a symposium on fractures and traumatic lesions presented by Drs. William Darrach, Stephen S. Hudack, Fred M. Smith, Barbara B. Stimson, Clay Ray Murray and Harrison L. McLaughlin.

New Tuberculosis Hospital.—Mayor La Guardia laid the cornerstone of the new Triboro Hospital for Tuberculosis on Grand Central Parkway, Queens, September 28. The new hospital, scheduled for completion in April 1940, will be nine stories high. It will have a capacity of 550 beds, divided mainly into six-bed wards occupying the third to the seventh floors. All floors will have solariums, and wide use is to be made of glass, notably in partitions between wards and in the large number of outside windows. The building is financed by a city appropriation of \$1,850,569 and a PWA grant of \$1,649,431.

Annual Plastic Surgery Meeting.—The eighth annual meeting of the Society of Plastic and Reconstructive Surgery was held in New York October 27-28. Features of the program included a symposium on skin grafting by Drs. James Barrett Brown, St. Louis, and Edward A. Kitlowski, Baltimore, a session of motion picture films and clinics Saturday morning. Papers were presented by Drs. Gustave Aufricht on "Details and Technical Hints on Rhinoplasty"; Adalbert G. Bettman, Portland, Ore., "Rebuilding the Alveolar Process and the Buccal Sulcus"; Jacques W. Maliniac, "Blood Supply of the Breast," and Leon E. Sutton, Syracuse, N. Y., "The Use of Tubed Flaps for the Study of Healing in Human Skin."

NORTH CAROLINA

Health Education Project.—Stanley County has been chosen by the state board of health and the state board of education for a project in health education in public schools, the first of a program to be financed by a \$50,000 grant from the Rockefeller Foundation. The program is designed to bring about closer cooperation between the departments of health and education and will provide classroom training for pupils in hygiene and related subjects, physical education, medical supervision from the point of view of health promotion and disease prevention, and training in home, school and community sanitation. Dr. John F. Kendrick, Raleigh, has been assigned temporarily by the International Health Division of the Rockefeller Foundation to direct the project.

District Meetings.—The annual meeting of the Sixth Council District of the Medical Society of North Carolina was held September 21 in Durham. The speakers included Drs. Oren Moore, Charlotte, on "The Problem of Abortion"; Charles R. Bugg, Raleigh, "Acute Contagious Diseases of Childhood," and William M. Nicholson, Durham, "Management of the Ambulatory Diabetic."—The Ninth District Medical Society held its annual meeting in Morganton September 28 with the following speakers: Drs. Roy H. Long, Morganton, on "Metrazol in the Treatment of Mental Disease"; James W. Davis, Statesville, "Treatment of Fractures of the Hip Joint"; Samuel M. Bittinger, Black Mountain, "Surgical Treatment of Tuberculosis"; Thomas D. Sparrow, Charlotte, "Rationale of the Treatment of Goiter," and Robert A. Ross, Durham, "Problems of Late Toxemia of Pregnancy." Dr. James W. Vernon, Morganton, paid tribute to the memory of the late Dr. Edward W. Phifer, Morganton, and Dr. James K. Hall, Richmond, gave an address entitled "What Moves Man."

OHIO

Society's Lecture Program.—The Mahoning County Medical Society presented its fall lecture program October 9-11 with Dr. Charles F. Geschickter, Baltimore, as the speaker. Dr. Geschickter dealt with lesions of the skin and oral cavity, the bone, soft parts, gastrointestinal tract, thoracic cavity and the breast.

Society News.—Dr. Austin A. Hayden, Chicago, addressed the Cincinnati Academy of Otolaryngology October 23 on "Otolologists, Hearing Aids and Leagues for the Hard of Hearing."—Dr. Albert M. Snell, Rochester, Minn., addressed the Montgomery County Medical Society, Dayton, November 17 on "Treatment of Liver Disease with Special Reference to the Hemorrhagic Diathesis."

OKLAHOMA

Regional Meeting.—The Southeastern Oklahoma Medical Association held a meeting in Poteau October 24. The following speakers were on the program:

- Dr. Orville M. Woodson, Poteau, Nephropthosis.
- Dr. Sidney J. Wolfermann, Fort Smith, Ark., Diagnosis of Location of Intestinal Obstruction.
- Dr. Leonard S. Willour, McAlester, Fractures of the Pelvis and Upper End of the Femur.
- Dr. Coyne H. Campbell, Oklahoma City, Hysteria.
- Dr. Charles T. Chamberlain, Fort Smith, Vitamin Deficiency Diseases.
- Dr. Paul Neeson Rolle, Poteau, Artificial Feeding of Infants.

Annual Railway Physicians' Meeting.—The thirty-eighth annual meeting of the Frisco System Medical Association was held at Tulsa, October 23-24. Among the speakers were:

- Dr. William G. Norman, Cherryvale, Kan., Economic Problems of Modern Medical Practice.
- Dr. Harry B. Davis, Kansas City, Mo., Ocular Conditions Encountered by the Railroad Surgeon.
- Dr. Edward H. Cary, Dallas, Texas, The Use of Old Tuberculin in the Diseases of the Eye.
- Dr. William S. Horn, Fort Worth, Texas, Chronic Brucellosis as a Major Cause of Neurasthenia.
- Dr. Robert M. Howard, Oklahoma City, Toxic Goiter.
- Dr. Cyrus E. Burford, St. Louis, Injuries by External Force to Kidney, Bladder and Urethra.

PENNSYLVANIA

State to Distribute Serum and Sulfapyridine for Pneumonia.—The state department of health recently designated pneumonia control centers throughout the state from which sulfapyridine and a certain amount of serum are to be distributed free at the request of physicians for patients who are not in a position to purchase them. The centers are also equipped to give rapid and accurate bacteriologic diagnosis. Clinical reports on the results of therapy on forms supplied by the state health department are required from each physician who uses sulfapyridine or serum supplied by the department.

Society News.—Dr. Henry J. John, Cleveland, addressed the Washington County Medical Society, Washington, November 8 on diabetes.—Dr. Charles Howard Marcy, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, November 2 on pulmonary hemorrhage.—Dr. Henry L. Bockus, Philadelphia, addressed the Delaware County Medical Society, Chester, November 9 on chronic gastritis.—Dr. Katharine O'Shea Elsom, Philadelphia, addressed the Dauphin County Medical Society, Harrisburg, October 10 on "Nutritional Disturbances Incident to Vitamin B Deficiency."—Dr. Henry K. Mohler, Philadelphia, addressed the Harrisburg Academy of Medicine October 17 on "Therapeutic Uses of Sulfanilamide and Its Associated Compounds."

TENNESSEE

Clinical Congress in Chattanooga.—The Chattanooga and Hamilton County Medical Society held its annual clinical congress October 26 at Newell Sanitarium and Erlanger Hospital. Dr. Julius C. Brooks was in charge of surgical clinics and Dr. James D. L. McPheeters in charge of medical clinics. Guest speakers at a banquet in the evening were Drs. James E. Paullin, Atlanta, Ga., on "Treatment of Congestive Heart Failure" and William H. Stewart and Charles W. Breimer, New York, on "Cineeroentgenography of Today."

Society News.—Dr. Robert R. Brown addressed the Nashville Academy of Medicine and the Davidson County Medical Society October 31 on "Internal Derangements of the Knee Joints" and Dr. William C. Dixon November 7 on "Treatment of Uterine Prolapse."—Drs. Jefferson A. Hanna and William C. Chaney, Memphis, among others, addressed the Dyer, Lake and Crockett Counties Medical Society October 4 on "The Present Conception of Vitamin Therapy" and "More Recent Advances in the Treatment of Migraine" respectively.—Dr. Stewart Lawwill, Chattanooga, addressed the Chattanooga and Hamilton County Medical Society November 2 on "Intracapsular Cataract Extraction."

TEXAS

South Texas Postgraduate Meeting.—The eighth annual Postgraduate Medical Assembly of South Texas will be held in Houston December 5-7 at the Rice Hotel. The lecturers will be Drs. George G. Ornstein, Eliot Bishop, Herbert F. Traut, James W. White and Rupert Franklin Carter, New York; Henry H. Turner, Oklahoma City; Frank R. Ober, Boston; Grady E. Clay and Edgar G. Ballenger, Atlanta, Ga.; Perry G. Goldsmith, Toronto, Canada; Harold I. Lillie, Rochester, Minn.; Archibald L. Hoyne, Chicago; Hans H. F. Reese, Madison, Wis., and Isaac A. Bigger, Richmond, Va.

UTAH

State Medical Election.—Dr. Alfred C. Callister, Salt Lake City, was chosen president-elect of the Utah State Medical Association at the meeting of the house of delegates during the Rocky Mountain Medical Conference in Salt Lake City in September. Dr. George M. Fister, Ogden, became president and the following vice presidents were elected: Drs. Edwin M. Neher, Salt Lake City; Wilford J. Reichmann, St. George, and David E. Ostler, Richfield. The 1940 meeting will be in Ogden.

VERMONT

Dispensary Enlarged.—The Burlington Free Dispensary, operated jointly by the University of Vermont College of Medicine and the city of Burlington, marked the twenty-fifth anniversary of its founding by opening new and enlarged quarters. The university rented and remodeled a building and will pay the rent and maintenance, while the city contributes \$5,000 for expenses and a part of the salary of the director. The dispensary is the teaching outpatient clinic for the medical school. The new facilities include a laboratory and diagnostic appliances. In addition it is planned to add new clinics in psychiatry and venereal disease. The dispensary occupies two floors of its new building, one floor is leased to relief agencies and the upper floor has rooms for students who are on twenty-four hour duty. Dr. Jesse A. Rust Jr. is city physician and director of the dispensary.

VIRGINIA

Special Society Elections.—Several societies of specialists held their annual meetings in Richmond during the recent annual meeting of the Medical Society of Virginia. The Virginia Urological Society elected the following officers: Drs. Albert A. Creecy, Newport News, president; Samuel Beverly Cary, Roanoke, vice president, and Linwood D. Keyser, Roanoke, secretary. New officers of the Virginia Radiological Society are Drs. Fred M. Hodges, Richmond, president; Daniel D. Talley Jr., Richmond, vice president, and Vincent W. Archer, Charlottesville, secretary. The Virginia Pediatric Society elected Drs. Samuel A. Anderson Jr., Richmond, president; James V. Bickford Jr., Norfolk, vice president, and John M. Bishop, Roanoke, secretary, reelected. Dr. Harry Hudnall Ware Jr., Richmond, was elected president of the Virginia Obstetrical and Gynecological Society and Dr. Henry C. Spalding, Richmond, secretary.

WISCONSIN

Fiftieth Anniversary of County Medical Society.—The Douglas County Medical Society celebrated its fiftieth anniversary at a meeting in Superior October 4 with Dr. John Baird, the only surviving charter member, as the guest of honor. Dr. Fred G. Johnson, Iron River, councillor of the eleventh district, and several colleagues paid tribute to Dr. Baird, and the society presented to him a gold medal in recognition of his services to the society, the community and the medical profession. A volume on the history of the society, prepared by Mrs. Loran W. Beebe, Superior, was presented by the woman's auxiliary.

Society News.—Dr. Conde F. Conroy, Milwaukee, addressed the Brown-Kewaunee-Door County Medical Society, Green Bay, October 19 on management of varicose veins.—Drs. Alexander R. MacLean and John L. Emmett, Rochester, Minn., addressed the Eau Claire-Dunn-Pepin Counties Medical Society October 30 in Eau Claire on "Vascular Headache" and "Urinary Retention" respectively.—Speakers at a meeting of the Grant County Medical Society, Lancaster, October 25 were Drs. John C. Pickard, Dubuque, Iowa, on "The Ear, Nose and Throat in General Practice"; Horace Kent Tenney Jr., Madison, "Vomiting in the Newborn"; Walter C. Alvarez, Rochester, Minn., "Treatment of Indigestion," and Marcos Fernan-Nunez, Milwaukee, "Cancer—Its Prevention and Control."—Dr. William J. Bleckwenn, Madison, addressed the Green Lake-Wausau County Medical Society, Princeton, October 24 on "The Use of Barbiturates in General Practice."

WYOMING

State Medical Election.—Dr. Peter M. Schunk, Sheridan, was named president-elect of the Wyoming State Medical Society at the recent annual meeting of the house of delegates during the Rocky Mountain Medical Conference in Salt Lake City in September. Dr. Roscoe H. Reeve, Casper, was elected vice president and Dr. Marshall C. Keith, Casper, reelected secretary. Dr. John H. Goodnough, Rock Springs, became president. Next year's meeting will be in Sheridan.

GENERAL

GOVERNMENT SERVICES

Impostor Sells Surgical Supplies.—William R. Warner and Company, St. Louis, has reported an impostor said to be selling surgical supplies in Chicago under the name "Warner and Company." The man is said to be about 50 years of age and of dignified appearance. In some instances he has used the name of "Mr. Warner," according to the report. In making these alleged sales, for which he has been receiving deposits, this man uses a duplicate sales order book and a red rubber stamp "Warner and Company."

Physician in China Appeals for Medical Books.—The American Library Association has received an appeal from a physician on the staff of the Methodist Mission, Lingling, Hunan, asking for medical books. Dr. Vilma Lasser writes: "I am in great need of surgical books, especially those concerning obstetrics or treatment of tropical diseases in English, German or French. I lost all my books when the Hudson Taylor Memorial Hospital was destroyed in the great fire at Changsha in November last year." Dr. Lasser originally wrote to the American Library Association concerning books which that association is collecting for Chinese libraries, but the association states that probably little can be done through that channel.

Specialists Urge Care for Handicapped Children.—The American Academy of Ophthalmology and Otolaryngology at its annual meeting in Chicago in October adopted a resolution urging that funds be provided by foundations and other appropriate agencies to give attention to children with visual, hearing and speech defects. The resolution recommended that adequate programs be instituted to detect these deficiencies which constitute an actual or threatened handicap to school children and to provide, through the cooperation of qualified specialists in national, state and local medical societies, appropriate medical care for indigent and underprivileged children who may be afflicted or threatened with such handicaps. The American Laryngological Association passed a similar resolution at its recent meeting.

Special Society Elections.—Dr. Arthur J. Schwenkenberg, Dallas, Texas, was named president-elect of the Southern Psychiatric Association at the annual meeting in Louisville, Ky., in October. Dr. William E. Gardner, Louisville, was elected vice president and Dr. Newdigate M. Owensby, Atlanta, as installed as president and Jacksonville, Fla., as installed as president for next year's meeting. Dr. Paul A. Turner, Louisville, Ky., was elected president of the Southern Tuberculosis Conference at the annual meeting in Charleston, S. C., in October. The 1940 meeting will be in Monroe, La. Dr. William B. Porter, Richmond, Va., was elected president of the American Clinical and Climatological Association at the annual meeting at Saranac Lake, N. Y., in October and Dr. Francis M. Rackemann, Boston, was reelected secretary.

Meeting of Tropical Medicine Groups.—The American Society of Tropical Medicine will hold its thirty-fifth annual meeting in conjunction with the American Academy of Tropical Medicine and the National Malaria Committee November 21-24 in Memphis, Tenn. William H. Taliaferro, Ph.D., Chicago, will deliver the fourth Charles Franklin Craig Lecture Tuesday November 21 on "The Mechanism of Acquired Immunity to Metazoal Parasites," and the Walter Reed Medal will be awarded to Dr. William B. Castle, Boston. Dr. Alfred C. Reed, San Francisco, will deliver his presidential address at the annual luncheon of the society November 23 on "The Future of Tropical Medicine." Among speakers on the program will be:

Dr. Edward B. Vedder, Washington, D. C., A Discussion of the Etiology of Sprue with a New Hypothesis.
Dr. Alvin E. Keller, Nashville, Tenn., Studies of Hookworm Disease in Six Southern States During the Period of 1930-1938.
Drs. Thomas B. Magath, Rochester, Minn., and Henry E. Melency, Nashville, Tenn., The Complement Fixation Reaction for Amebiasis.
Dr. Lowell T. Coggeshall, New York, The Selective Action of Sulfanilamide in Malaria.
Dr. Harry Most, New York, Malignant Malaria in Drug Addicts; Epidemiologic, Clinical and Laboratory Studies.

The sixth annual dinner of the American Academy of Tropical Medicine will be held Thursday evening. William W. Cort, Ph.D., Baltimore, will deliver his presidential address on "Research on Helminth Diseases and Public Health Progress" and the second award of the Theobald Smith Medal of George Washington University will be made to Dr. Richard P. Strong, Boston.

Fellowships for Women Physicians.—The Women's Medical Association of New York offers two Mary Putnam Jacobi fellowships for 1940. One of \$500, available January 1,

will be given to an American woman physician to carry on or complete some special problem in medical research. Applications must be in by December 1. In addition, the regular fellowship of \$1,000, available October 1, is open to any woman physician, American or foreign. Applications for this fellowship must be received by March 1, 1940. For both fellowships applicants must be graduates of reputable medical schools. Applications should be filed with the secretary of the committee and must be accompanied by statements as to health, educational qualifications, previous work and a proposed problem for investigation and by a photograph of the applicant. The secretary is Dr. Phebe L. Dubois, 150 East Seventy-Third Street, New York.

Southern Medical Association.—The thirty-third annual meeting of the Southern Medical Association will be held in Memphis, Tenn., November 21-24, at the Municipal Auditorium, under the presidency of Dr. Walter E. Vest, Huntington, W. Va. Tuesday November 21 will be "Memphis Day" with several clinical sessions making up the program. Dr. Rock Sleyster, Wauwatosa, Wis., President of the American Medical Association, will be among the speakers at a general session Wednesday, on "What Price Depression?" Among guest speakers at meetings of the nineteen sections will be:

Dr. Fritz B. Talbot, Boston, Present Status of the Endocrine Diseases of Childhood.
Dr. Florence Rena Sabin, Denver, Colo., Cellular Reactions to a Marked Antigen.
Dr. Henry Alsop Riley, New York, Some Observations on the Mechanism of Headache and Migraine.
Dr. Arnold D. Jackson, Madison, Wis., Surgical Treatment of Diseases of the Biliary Tract.
Dr. Ralph K. Ghormley, Rochester, Minn., Study of Acute Infectious Lesions of the Intervertebral Disks.
Dr. Charles E. Galloway, Evanston, Ill., An Evaluation of Glycocalculus.
Dr. Alexander Randall, Philadelphia, Etiology of Primary Renal Calculus.
Dr. Harry S. Gradle, Chicago, Glaucoma Errors That I Have Made and That I Have Seen.
Dr. Ernest L. Stebbins, Albany, N. Y., Recent Studies of Epidemic Diarrhea and Dysentery.

There will be a public meeting Tuesday evening with the following program:
Dr. Seale Harris, Birmingham, Vitamin Facts and Fads.
Dr. Irvin Abell, Louisville, Ky., Some of the Contributions of Medicine to Public Welfare.
Rev. Alphonse M. Schmittalla, St. Louis, Society's Debts to the Doctor.

CORRECTION

Address of Dr. G. Marshall Crawford.—In the title of the paper by Crawford and Ray in THE JOURNAL, November 4, page 1715, the address of Dr. G. Marshall Crawford should have been Boston. The error came about by changing Dr. Leon F. Ray's address from Boston to Portland, Ore., and failing to insert Boston under Dr. Crawford's name.

Government Services

Physicians Wanted in the CCC

A recent decision of the director of the CCC and the War Department permits the employment of physicians who are not medical reserve officers in this service. The principal duties at camps consist of the medical care of the enrollees and the practice of preventive medicine. To be eligible, the physician must be legally qualified to practice medicine and physically able to perform the duties involved. No quarters are provided for families and the physician will be required to pay for his own food at camps. Temporary quarters will be provided for a nominal fee. Those selected will be required to pay for his own traveling expenses to the nearest district headquarters, where they will be put on temporary duty for instruction before being sent to camps. Traveling expenses incurred in the transfer from the district headquarters to camps or from one camp to another will be paid by the government. Physicians interested in this type of service are requested to submit their applications to the office of the Surgeon, Headquarters of the Seventh Corps Area, Federal Building, Omaha, giving date when available and preference of assignment in the following states: Minnesota, North Dakota, South Dakota, Iowa, Nebraska, Missouri, Kansas and Arkansas. Attention is directed to a change in the initial salary for physicians employed in the Civilian Conservation Corps. The salary was changed October 10 from \$2,600 per year to \$3,200.

Foreign Letters

PARIS

(From Our Regular Correspondent)

Oct. 11, 1939.

American Hospital of Paris

The American Hospital with its 500 beds, its fine equipment and its staff of physicians and selected nurses has just been placed by Dr. Gros, its superintendent, at the disposal of French war victims. Hospital services have been transferred to Etretat on the coast of Normandie, where 1,500 wounded or sick can be accommodated. On the other hand, a certain number of French hospitals have been closed, either because of the difficulty of evacuation in case of bombardment or because of the considerable reduction in the number of inhabitants of Paris in consequence of mass migrations.

Treatment of Craniocerebral War Wounds

The Académie de chirurgie held its opening fall session September 20. Gosset sent a cordial welcome with the best wishes of the members to all French and allied surgeons. He proposed a work plan and expressed the hope that the inter-allied medical conferences conducted during the World War at Val de Grâce at the initiative of Mr. Lloyd George would be revived because of their great usefulness. The principal papers of this meeting were devoted to craniocerebral wounds and their treatment and were read by Thierry de Martel, the distinguished surgeon of the American Hospital of Paris, and Clovis Vincent, professor of neurosurgery in the medical faculty of Paris. Vincent arrived at cerebral surgery by way of neurology and de Martel by way of general surgery. De Martel modestly acknowledges his indebtedness to Cushing and Mackenzie. The two papers differed on certain points but were in general agreement. For that reason they are reviewed together. A neurosurgical operation in itself constitutes a craniocerebral trauma. The physiopathologic sequels are the same and the technics of attack on the cerebral tissue are analogous. However, there is a considerable difference in the traumatic agents and likewise important differences between war wounds and ordinary traumas, such, for example, as are due to automobile accidents.

In an automobile accident, a head weighing 17.6 pounds (8 Kg.), considered as a projectile and launched at the rate of 72 kilometers an hour, on striking an object effects an impact equivalent to 160 kilogrammeters. The surface area involved is wide. In a war wound, however, caused for example by a bullet of 15 Gm. projected at 450 meters per second, the bullet attains an impact effect of 150 kilogrammeters. However, the surface involved is small. In the former case manifold lesions may be observed as well as significant concussion effects; in the latter, the lesions are concentrated and deeper; often the damage done on the surface is negligible compared with that to the nervous tissue. Today, with the progress that has been made in surgery of the cerebral tissues, one ought to bring about healing in many more cranial wounds and, above all, prevent better than was formerly possible the horrible effects which overshadowed the prognosis of those surgically cured. For that reason, speed is of utmost importance. The wounded should be brought to the surgeon before the appearance of edemas destructive to the brain, especially near the gray columns and the bulb. Early intervention prevents in the great majority of cases the principal risks of traumas and interventions, namely, hematomas, cerebral hernias or fistulas of the cerebrospinal fluid, excessive loss of bony substance and disastrous cicatrizations which affect the skin, bone and cerebral tissue and induce epilepsies and mental disorders. These benefits cannot be realized unless the surgeon

is competent and well supplied with the necessary equipment: head equipment, mechanical trephines, Cushing-Mackenzie clips, electrocoagulation apparatus of high frequency, low voltage and of weak intensity, wax to close osseous orifices, refractors, aspirators, irrigators for warm solutions, and black silk which resists decomposition. Anesthesia will be local preferably. Epileptic crises will be forestalled or managed with barbiturates, chlorol and bromides intravenously administered. Systematic roentgenography will reveal the presence of a projectile and bony splinters. A shutter will be made in the cranium according to the de Martel method, which enlarges the operative field. Its hinge will be made of muscular or aponeurotic tissue. The dura mater ought to be attached to the cranial periosteum or the deep wound portions by a fine catgut suture and its hemostasis assured by means of clips or electrocoagulation. Lesions of the cerebral tissue will then be clearly in view. Contused portions will be removed by means of scissors.

The delicate matter of hemostasis with its inundation in the absence of definite blood vessels will be managed by the aspirator. It will show the bleeding points and indicate where clips should be used or coagulation performed with low current. At times, especially if a deeply embedded bullet is to be removed, it will be necessary to make a complementary cranial shutter. On completion of hemostasis suture is made. Whenever possible, one ought to suture along the galea, because it resists cerebral pressure better than the elastic skin of the scalp. The most difficult part of this surgery seems to be hemostasis of the sinuses. It is here that experience and surgical skill will be important. According to Vincent, brain surgery is a part of general surgery and can be easily learned. There are in France quite a few capable brain surgeons, but the number of wounded may require additional specialists. Lenormant would like to see centers created for the treatment of cranial wounds and for the instruction of physicians at the front on indications for immediate action in lesions of the skull and cerebral tissue.

French Scientific Societies

Some other societies have canceled their fall meeting and among them are the Society of Dermatology and Syphilography, which was to meet in Paris October 12-14, and the cancer society scheduled for October 8.

BERLIN

(From Our Regular Correspondent)

Sept. 20, 1939.

Mothers of Large Families in Germany

In the census of 1933, restricted to Germany before its territorial conquests, were registered 3,577,000 married women, exclusive of widows and divorcées, with four or more children, which is 24.7 per cent of all married women. Of these, 1,148,000 had four children and the remaining five or more. Of the latter, 735,000 had five children, 869,000 had six or seven children and 825,000 had eight or more. In the period between the middle of 1933 and the beginning of 1939 the number of married women with four children and more decreased by 160,000 (those with four or five by 80,000; those with six or seven by 30,000 and those with eight or more by 50,000). On the other hand, the total number of married women during the same period of time increased by about 1,563,000 to a total of 16,061,000. Widows and divorced women, not included in the figures given here, with four or more children were reported at the beginning of 1933 to total 1,600,000; with four or five children 750,000, with six or seven children 400,000 and with eight or more children 450,000.

Therapy by Fasting

The Frankfurter medizinische Gesellschaft recently considered the question of fasting. H. E. Meyer first discussed the basic principles underlying the therapeutics of fasting. During

the first days of fasting, he said, a brief diminution of nitrogen excretion is followed by an increased excretory activity. Urea elimination keeps pace with the level of the total nitrogen excretion until the end of the first week of fasting. This is followed by a decrease, as part of the nitrogen is contained in the increased elimination of ammonia induced by acidosis. Very little uric acid is excreted from the time fasting is begun. Modifications of nitrogen elimination during the first week are related to the carbohydrate level. No observations were made that would indicate an increased retention of urea and uric acid before fasting therapy was initiated. There is, however, a great probability that intermediary metabolic products are excreted in increased quantities, especially during the first week. What the nature of these products is is not clear. A part of them belongs to the group which can be detected in the xanthoprotein test. Patients with high arterial blood pressure and chronic constipation show an especially high excretion of xanthoproteins. Control of oxygen eliminated shows that after an incipient deterioration of oxidation, oxidation improves more favorably than before fasting. In capillary microscopy one can clearly observe a diminution of the abnormally heightened capillary tonus. It invites the reflection that the increased elimination of intermediary metabolic products, which in turn participate in the decompensatory peripheral processes, represents a contributing cause in its favorable effect on circulatory diseases, especially in cases of high arterial blood pressure.

Changes in the metabolism of carbohydrates and fats are characterized by the sudden and marked development of acetone during the fifth and tenth day of fasting. However, an increased ketosis does not occur. Since the body manifestly adjusts itself readily to a diminution of glycogen, the elimination of acetone decreases again within a few days to an almost normal level. Feeding with grape sugar frequently demonstrates, beginning with the third week, a marked secondary hypoglycemia. The acidity crisis contributes essentially to cause a change of the organism, which change, in turn, mobilizes the defensive forces of the organism. This can be clearly seen in the heightened bactericidal power of the blood.

BELGIUM

(From Our Regular Correspondent)

Oct. 18, 1939.

Pensions for Aged Physicians

A most important corporate reform is under way, namely, the establishment of a pension system for aged physicians. The medical profession of Brussels cordially favors the idea that the directors of the Federation of Belgian Physicians follow the example set by the French, who have demonstrated what the members of a profession still entitled to be called liberal can accomplish without the support of the state. The plan is approved by the French medical syndicates, which represent four fifths of the physicians practicing in France and in the colonies. Actuarial computations are in progress. Within two years, no doubt, several thousands of aged physicians can retire and be entitled to at least a partial pension. It would be unfair to allot to them the full or normal pension in view of the fact that no assessment has been levied on them. However, they will receive about 8,000 francs if they make no contribution and 10,000 if they can contribute a small amount, equivalent to 5 per cent of 1,000 francs. The younger members of the profession will receive, at the time of retirement, from 25,000 to 29,000 francs. The highest premium will probably be 3,000 francs. Certain other risks are also taken into account, such as half pensions for widows, reimbursement for funeral expenses and special grants for physical disability.

Socialized Medicine

Before the Société médico-chirurgicale of Brabant, M. Schwes initiated a discussion on present tendencies in medical organization, championing the private character of the physician's status and practice. He asserted that private practice should remain the basis of all plans of organized medicine and that mass medicine was not feasible either from the financial or from the social point of view. The results would be disastrous. His statement evoked much criticism; although the assembly agreed that it was undesirable to see medicine converted into a state function, yet it was true that relations between medicine and the state should exist and develop. On the problem of the relation of medicine to the state, Massion presented the following point of view: The state cannot practice medicine in the current sense of the word. Freedom of choosing one's physician and the confidential character of his services must be rigorously respected in medical practice as the foundation of the healing art. The role of the state, however, is great. It must stimulate, direct and supplement, laboring to place medical service within the reach of all. The physician, while refusing to allow the fundamental character of his medical acts to be altered, ought to work in cooperation with the state for a better public health and a better medical service. An exclusively negative attitude like that of Schwes was not tenable, he said. Medicine cannot ignore the state, nor can the state divest itself of an interest in the organization and solution of the pressing problems of public health.

The New Tumor Center in Brussels

The Institute Jules Bordet, replacing the Centre des tumeurs de l'hôpital Brugmann, which had outgrown its usefulness, was recently dedicated. The building is constructed on the two wing plan. One wing, with eight stories, is intended for hospitalization; the other, six stories high, is given over to rooms and quarters for the examination of patients, for roentgenography and diagnosis, for apparatus for radium therapy, for surgical rooms and for laboratories and libraries. The eight story wing contains an auditorium and museum, administrative offices and consultation rooms for heads of departments, wards and rooms for hospital service, and the kitchen and dining rooms for the medical staff, nurses and relatives of the patients. The public aid committee has assumed the task of the construction of the building. The university has furnished the money for the acquisition of a part of the land and the x-ray, the scientific and the diagnostic equipment necessary for the treatment of cancerous patients as well as for the study and instruction of cancerology. Thanks to the National Funds for Combating Cancer, the institute has 6.5 Gm. of radium.

Scientific control will be vested in the university and hospital service in the Committee on Public Aid. The new center has been named the Jules Bordet Institute as a tribute to an eminent scientist of whom Belgium is proud.

Tuberculosis Among Workers in Tobacco Factories

Dr. Peremans reported (*Arch. de méd. soc. et d'hyg.* 1938, number 8) the results of his investigations in the Van der Elst tobacco factory at Louvain. Only workers directly in contact with tobacco were considered; these numbered 876, of whom 317 were men and 559 women. The average age was respectively 37 and 26, and the average work duration respectively eighteen and nine years. The workers examined were classified as: (1) those who had no notable pulmonary lesion, (2) those who had inactive pulmonary lesions and (3) those who had active pulmonary lesions. Cardiac and bone anomalies were also noted. Of the 317 men, twenty-four were found with active and sixty-seven with inactive pulmonary tuberculosis, twenty-four with cardiac lesions and five with bone anomalies. The figures for the women were respectively eleven, seventy, fifteen and four. Of the thirty-five suspected male and female

workers of the third group, thirty-four were given clinical tests with the following results: Active open tuberculosis appeared in two men and two women, active closed tuberculosis in eight men and four women, inactive tuberculosis in twelve men and five women and nontuberculous lesions in two men. The summarized report on the 876 workers indicated the following distribution: (1) sixteen cases (1.82 per cent) of pulmonary tuberculosis in evolution in four of which (0.45 per cent) there were open lesions, and (2) 154 cases (17 per cent) of inactive pulmonary tuberculosis. A comparison of these figures with those for other industries warrants the assumption that morbidity due to tuberculosis is practically no higher among workers in tobacco factories, on the average, than among workers in other industries.

FINLAND

Goiter as a National Problem

While goiter has been given much prominence in certain countries such as Switzerland, little is known in the outer world of the goiter problems with which Finland has to cope. Even in Finland itself there has hitherto been an inadequate appreciation of the nature and extent of these problems, and it is largely owing to the studies of Dr. Johannes Wahlberg, conducted during the past fifteen years, that a more or less comprehensive survey of the situation has now been made.

The area in which goiter is endemic corresponds almost exactly to that part which was dry mainland at the end of the ice period, when much of what is now high and dry was under the sea. In some parts, 10 per cent of the young men of military age have been found to present enlargement of the thyroid gland, and as the ratio of males to females suffering from goiter is about 1 to 5, it will be realized how prevalent this ailment is in the worst goiter districts. In the Pathological Institute in Helsingfors about 300 cases have been investigated in the course of a few years; in his clinical work, Dr. Wahlberg has dealt with 2,350 cases. The most characteristic feature of the endemic in Finland is the remarkably high frequency with which the enlargement of the thyroid is adenomatous; in the larger thyroids, adenomatous enlargements are demonstrable on palpation in about 90 per cent, and when the gland is subjected to a histologic examination it is most rare not to find any adenomatous changes.

There are still some doubts as to the wisdom of Finland following the example of Switzerland in the matter of iodine prophylaxis. May it not, it is asked, be wiser to wait and see how the Swiss, who have been given prophylactic doses of iodine throughout childhood, behave in adult life? Meanwhile, operative treatment in the most serious cases seems still to be the most effective, most economical and most speedy remedy.

The Growing Frequency of Abortions

The changed outlook from the moral and social points of view of the community in the matter of induced abortions has lately been demonstrated in a statistical study by Dr. Aulis Apajalahti of Helsingfors. His study deals with 21,007 cases of abortion admitted to the public hospitals in Helsingfors in the period 1901-1937. When the number of abortions was compared with the number of women of child-bearing age in Helsingfors it was found that the ratio of the one to the other had increased more than six times—from 1.9 to 12.5 per thousand. While the frequency of abortions has gone up by leaps and bounds, the birth rate has declined even more dramatically. For example, in the period 1907-1909, the birth rate, expressed in terms of the number of births per thousand women of child-bearing age, was 80.2. In the period 1934-1936 the corresponding figure was only 27.

Dr. Apajalahti notes that in 1936 the population of Finland was 3,807,163, and he quotes the somewhat gloomy prognostica-

tion of an unnamed statistician who has calculated that the population will never exceed 4 millions. Be this as it may, the attitude of women today toward the induction of abortion must be different from what it was only a generation ago. In the period under review, the ratio of febrile abortions in the public hospitals in Helsingfors to the total number of pregnancies has increased sixty-six times, i. e. from 0.2 to 13.5 per cent of all pregnancies. On the other hand, the ratio of afebrile abortions has in the same period increased only sevenfold, i. e. from 2.2 to 14.3 per cent. The calculation is also made that though all ages are involved in this rising tide of abortions, for the most part presumably induced, it is in the group below the age of 30 that this rise is most marked. As is to be expected, it is the unmarried woman whose pregnancies are most liable to end in induced abortions. Indeed, at the present time, the chances are that 67 per cent of the pregnancies of unmarried women will end in abortions.

Vaccination Problems

Until a few years ago Finland seemed to be immune to those sequels to vaccination which have caused great uneasiness in other European countries such as Holland and England. In 1932 the first cases of encephalitis following vaccination were reported. These cases—there were only four—were, however, enough to cause grave concern for the public health authorities already embarrassed by widespread neglect of vaccination in the country. After a careful consideration of every aspect of the subject, the public health authorities succeeded in framing a new vaccination law which came into force on Jan. 1, 1937. This law reflected recent experiences with regard to diseases of the central nervous system following vaccination, and provision was made for the wholesale vaccination of children before they reached that age at which encephalitis is most likely to follow vaccination. The law provides that children are to be vaccinated before the end of the calendar year in which they attain the age of 2 years. Neglect of this order is to be punishable. The effect of this law was a marked rise in 1937 in the number of vaccinations, which reached 162,877, or 56 per cent of all the children due to be vaccinated in that year. The corresponding percentage for 1935 was only 22.8, and for 1936 it was 33.9.

It was unfortunate that five new cases of acute disease of the central nervous system following vaccination should occur in 1937, the first year of the operation of the new vaccination law. Dr. Lars Grönlund, who has issued a special report on these five cases, has advanced a new theory as to the underlying causes of postvaccinal encephalitis. His theory hinges on the observation that in one of his cases, that of a girl aged 5 years, typical myasthenia gravis had developed at the age of 2. Dr. Grönlund suggests that the myasthenia gravis may have been a hormone-deficiency or a vitamin-deficiency disease, which lowers the resistance of the central nervous system to the usually harmless virus of vaccinia.

Gout

Dr. Van Breemen presented a study before the *Journées Médicales de Bruxelles* on the pathology of gout in the Netherlands. From the statistical point of view the disease is rare in this country. However, the disease exhibits a powerful interest: If gout did not exist, the history of the world would have a different aspect. Gout is no longer recognized by the practitioner with the facility which formerly characterized its diagnosis. Now as formerly the pathogenesis of gout, in spite of hundreds of investigations, is unknown. Its anamnesis, habitus, articular deviations, uric acid content in the blood, tophus and roentgen aspect have their value for diagnostic pur-

poses, but in different degrees. The speaker made observations on different diagnostic facts. Various forms like rheumatoid gout, chronic gout in women and the irregular type (atypical Goldscheider type) were observed; they are more frequent in the Netherlands than the classic type.

Religious Affiliation of University Students

University statistics furnish the following data on the religious preferences of students enrolled in the different faculties and departments:

The Biochemical Changes in Stored Blood

An attempt to obtain a more precise knowledge of the biochemical changes that take place in stored human blood has recently been made by Marjorie Biek, working at the Walter & Eliza Hall Institute, Melbourne. Seeking conditions under which blood might be stored for longer periods than has hitherto been possible, she has determined during storage the content of dextrose, urea, creatinine, nonprotein nitrogen, reduced glutathione and uric acid in whole blood and the ionic phosphate content of the plasma.

It was found possible to keep the blood from fourteen to seventeen days at 0 C. before any sign of hemolysis was observed. The onset of hemolysis appeared to be associated with two significant changes in biochemical composition, namely an increase in both the nonprotein nitrogen of the blood and the ionic phosphate content of the plasma. The dextrose content of the whole blood invariably decreased almost to zero before hemolysis began, but the artificial maintenance of a high concentration of dextrose only delayed hemolysis for a short period.

The behavior of blood stored under anaerobic conditions was also investigated. The results show that anaerobic conditions hasten the decrease of dextrose but are without effect on the development of the other changes observed.

Cells washed free from plasma with buffered saline solution, with or without the addition of dextrose, hemolyzed much more readily than did erythrocytes suspended in their own plasma, and the increase in nonprotein nitrogen was concurrently larger and more rapid. When, however, cells were washed and stored in buffered saline solution containing 8 per cent sucrose, their stability was markedly increased and the changes in the concentrations of nitrogenous constituents were slower. As the sucrose was dissolved in saline solution the erythrocytes were not agglutinated to any extent, so that any effect due to mechanical aggregation of the erythrocytes appeared to be excluded.

The very slight increase in the concentration of phosphate ions in stored plasma, compared with the high increase observed in whole blood, indicates that the ionic phosphate content has some connection with the hemolytic process.

The biochemical changes that take place do so almost entirely in the erythrocytes, but the essential nature of the process remains unknown.

Passive Immunity in Experimental Whooping Cough

Most investigators of prophylactic vaccination against whooping cough have stressed the need for some laboratory test to detect the appearance and duration of immunity. E. A. North and his colleagues working at the Commonwealth Serum Laboratories and the Children's Hospital in Melbourne have recently described methods for the demonstration of an antibody protecting mice against infection with *Haemophilus pertussis* when injected intranasally under anesthesia. This protective action, they state, is the result of the development of a specific antibacterial antibody in the serum following natural infection with *Haemophilus pertussis* or artificial immunization. The protective antibody was not present in the serums of non-immunized children who had not had whooping cough but appeared following prophylactic immunization. It was present in the serum of most adult contacts of patients with whooping cough following symptoms suggestive of mild infection but was not present in healthy young adults who had had no contact with these patients.

These workers conclude, therefore, that this antibody, demonstrable directly by the injection of mice, plays an important part in the resistance of children immune to whooping cough as the result of the natural disease or prophylactic vaccination.

Marriages

WILLIAM MORGAN FOX, Columbia, S. C., to Miss Peggy Sugg Williams of Raleigh, N. C., in Durham, N. C., September 23.

LEWIS EARL FRASER, Hiwassee Dam, N. C., to Miss Alice Jean Keith of Memphis, Tenn., at Carthage, Miss., September 2.

NICHOLAS AARON WHEELER JR., Lafayette, Ala., to Miss Caroline Carmichael in McDonough, Ga., October 5.

MALCOLM DOUGLAS HARRISON, Washington, D. C., to Miss Sadye Belle Dailey of Blanche, N. C., October 7.

PETER DARLING CRYNOCK, Morgantown, W. Va., to Miss Louella Wilson of Fairmont, November 4.

KERMIT WENDELL COVELL, Angola, Ind., to Miss Evelyn Dickson at Asheville, N. C., November 2.

MAVIS P. KELSEY, Rochester, Minn., to Miss Mary Randolph Wilson of Beaumont, Texas, September 17.

ALEX CHALMERS HOPE, Union, S. C., to Miss Virginia Nalle Campbell of Charlotte, N. C., October 5.

ROBERT MAZET JR., New York, to Miss Catharine Metz of Springfield, Ill., September 23.

LEON J. ANSON, New York, to Miss Betty H. Bowers of Johnstown, Pa., October 11.

JAMES EVERETT MOORE, Ashland, Ky., to Miss Fern Harris of Winchester, October 8.

WALTER NICKEL, Rochester, Minn., to Miss Mona O'Neil of Minneapolis, recently.

WILLIAM FITZGERALD, Chicago, to Miss Hilda Duffy of Sycamore, Ill., September 12.

JOSEPH MARCOVITCH, Dwight, Ill., to Miss Lillian Ganzer in Brooklyn, September 6.

FRANK C. HAMMOND to Mrs. Theresa A. McTurk, both of Philadelphia, recently.

PAUL DERANIAN, Indianapolis, to Miss Mary Frances Setser at Brooklyn, recently.

WILLIAM E. ABBOTT to Miss Molly Temple, both of Cleveland, September 23.

JACK HULL, Indianapolis, to Miss Princess Cogan of Peru, Ind., in September.

Deaths

Livingston Farrand ☉ Brewster, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; president from 1921 to 1937 and since 1937 president emeritus of Cornell University; instructor of psychology at his alma mater from 1893 to 1901, adjunct professor of psychology from 1901 to 1903 and professor of anthropology, 1903-1904; president of the University of Colorado, Boulder, from 1914 to 1919; treasurer of the American Public Health Association from 1912 to 1914; from 1905 to 1914 was executive secretary of the National Association for the Study and Prevention of Tuberculosis, now known as the National Tuberculosis Association, of which he was elected president in 1923; member of the Colorado State Medical Society; in 1939 chairman of the advisory committee of the American Red Cross and chairman of the central committee from 1919 to 1921; director of tuberculosis work in France of the International Health Board, Rockefeller Foundation, 1917-1918; Officer of the Legion of Honor of France; member of the board of trustees of the American Museum of Natural History; formerly chairman of the board of trustees of the Carnegie Foundation for the Advancement of Teaching, of the National Health Council, New York State Public Health Council, the special New York State Health Commission appointed in 1930 and the advisory council of the Milbank Memorial Fund; received degrees from numerous universities; author of "Basis of American History" published in 1904; editor of the *American Journal of Public Health*, 1912-1914; aged 72; member of the board of governors of the New York Hospital, where he died, November 8, of bronchopneumonia and empyema.

Robert Sonnenschein ☉ Chicago; Rush Medical College, Chicago, 1901; associate clinical professor of laryngology and otology at his alma mater since 1933; formerly professor of diseases of the ear, nose and throat at the Post Graduate Medical School; member of the American Academy of Ophthalmology and Otolaryngology, the American Laryngological Association, the American Laryngological, Rhinological and Otolological Society and the American Otological Society; fellow of the American College of Surgeons; past president of the Chicago Laryngological and Otological Society; member of the medical advisory board of the third district in Illinois during the World War; contributed a chapter on testing of hearing in Jackson and Coates's book "The Nose, Throat and Ear and Their Diseases," published in 1929, and a section on surgery of the ear in "A Text Book of Surgery" by Christopher, published in 1935; aged 60; since 1926 attending otolaryngologist to the Michael Reese Hospital, where he died, November 8, of paratyphoid infection and pneumonia.

Oscar H. Plant, Iowa City, Iowa; University of Texas School of Medicine, Galveston, 1902; professor of pharmacology at the State University of Iowa College of Medicine; instructor of physiology at the University of Texas, Galveston, 1901-1907, and assistant professor of physiology, 1907-1910; instructor of pharmacology, University of Pennsylvania, Philadelphia, 1911-1913, assistant professor of pharmacology, 1914-1918, and professor of pharmacology, 1918-1920; treasurer, 1929-1934, vice president 1935-1936, and president in 1939 of the American Society for Pharmacology and Experimental Therapeutics; in 1939 chairman of the executive committee of the Federation of American Societies for Experimental Biology; aged 64; died, October 2, of coronary sclerosis.

Charles Staples Mangum, Chapel Hill, N. C.; Jefferson Medical College of Philadelphia, 1894; member of the Medical Society of the State of North Carolina; since 1905 professor of anatomy, from 1933 to 1937 dean, from 1900 to 1905 professor of pharmacology and demonstrator of anatomy, and formerly professor of physiology and materia medica at the University of North Carolina School of Medicine; member of the American Association of Anatomists; aged 69; died, September 29, in a hospital at Durham of cirrhosis of the liver.

Louis Laval Williams ☉ Medical Director, U. S. Public Health Service, retired, Asheville, N. C.; Medical College of South Carolina, Charleston, 1880; was appointed assistant surgeon in the U. S. Public Health Service in 1885; for many years in charge of public health conditions at various immigrant stations; in 1920 was nominated by President Wilson assistant surgeon general at large; was retired in 1924; was made medical director in 1930 by an act of Congress; aged 79; died, September 17, of cerebral thrombosis.

Earl Lenwood Parmenter ☉ Lieut. Colonel, U. S. Army, retired, Mobile, Ala.; University Medical College of Kansas City, Mo., 1907; veteran of the Spanish-American and World

wars; was commissioned a major in the medical corps of the U. S. Army in 1920, and was retired for disability in line of duty Oct. 31, 1937, with rank of lieutenant; aged 59; died, August 27, in the Jackson Infirmary, Jackson, Miss., of cardiovascular disease.

John Wilson Tappan ☉ Surgeon, U. S. Public Health Service, El Paso, Texas; University of Virginia Department of Medicine, Charlottesville, 1898; entered the U. S. Public Health Service March 20, 1917, and retired Nov. 1, 1933; formerly city and county health officer; fellow of the American College of Physicians; aged 71; died, September 2, in the William Beaumont General Hospital.

Curtis Dudley Pillsbury ☉ Lieutenant Colonel, M. C., U. S. Army, Fort Crook, Neb.; University of Michigan Homeopathic Medical School, Ann Arbor, 1914; served during the World War; was commissioned a first lieutenant in the medical corps in 1917, in 1919 a major and in 1937 a lieutenant colonel; aged 50; was killed, September 29, when his car was struck by a truck.

George Arthur Neal ☉ South West Harbor, Maine; Baltimore Medical College, 1905; president and formerly secretary of the Hancock County Medical Society; for many years a member of the school board and at one time superintendent of schools; on the staff of the Mount Desert Island Hospital, Bar Harbor; aged 67; died, September 17, of angina pectoris.

John E. Douglas, Garrett, Ind.; Chicago College of Medicine and Surgery, 1913; member of the Indiana State Medical Association; assistant professor of clinical pathology at the Baylor University College of Medicine, Dallas, Texas, and pathologist of the hospital, 1929-1930; aged 52; died, September 23, of coronary thrombosis and chronic myocarditis.

Walter S. Stevens ☉ Oklahoma City; National University of Arts and Sciences Medical Department, St. Louis, 1912; at one time superintendent of the Choctaw-Chickasaw Sanatorium, Tahlequah; medical director of district number 5, Indian Service; aged 54; died, September 11, in St. Anthony Hospital of lymphatic leukemia.

Walter C. McFadden ☉ Shelbyville, Ind.; Medical College of Indiana, Indianapolis, 1902; past president of the Shelby County Tuberculosis Association; formerly secretary of the city board of health; on the staff and at one time superintendent of the W. S. Major Hospital; aged 60; died, September 30, of coronary occlusion.

James Dodd Dixon, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1902; member of the board of health of Lachine; fellow of the American College of Surgeons; surgeon to the Lachine General and St. Joseph Hospital; aged 60; died, September 27, in the Royal Victoria Hospital.

Charles Lloyd Egbert, Hastings, Neb.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; member of the Nebraska State Medical Association; medical director and superintendent of a hospital bearing his name; aged 60; died, August 26, of heart disease.

Rudolph Duenweg, Terre Haute, Ind.; University of Louisville (Ky.) Medical Department, 1913; member of the Indiana State Medical Association; fellow of the American College of Surgeons; on the staff of St. Anthony's Hospital; aged 48; died, September 24, at Culver, of coronary embolism.

Herbert Scott Pattee, Manchester, N. H.; University of Vermont College of Medicine, Burlington, 1913; member of the New Hampshire Medical Society; served during the World War; on the staffs of the Elliot and the Balch hospitals; aged 52; died, August 26, in Tilton, of coronary thrombosis.

Cecil Boner O'Brien, Greencastle, Ind.; Indiana University School of Medicine, Indianapolis, 1923; member of the Indiana State Medical Association; physician to the student health service, DePauw University; aged 42; died, September 7, in the Robert W. Long Hospital, Indianapolis.

Joseph Savage Alford ☉ Los Angeles; University of Pennsylvania School of Medicine, Philadelphia, 1908; member of the Colorado State Medical Society; aged 55; died, September 23, in the Veterans Administration Facility, Sawtelle, Calif., of coronary thrombosis.

Allen Romaine Long, Buffalo; University of Buffalo School of Medicine, 1921; member of the Medical Society of the State of New York; instructor of medicine at his alma mater; on the staff of the Deaconess Hospital; aged 42; died, August 25, of myocarditis.

John Humes Barnfield ☉ Logansport, Ind.; Jefferson Medical College of Philadelphia, 1886; for many years member

of the school board; on the staff of St. Joseph Hospital; aged 75; died, September 27, in the Methodist Hospital, Indianapolis, of heart disease.

Capers Capehart Jones, Birmingham, Ala.; Philadelphia University of Medicine and Surgery, 1870; member of the Medical Association of the State of Alabama; Confederate veteran; aged 93; died, September 7, of angina pectoris and arteriosclerosis.

William E. Craig, Joplin, Mo.; University of Kansas City Medical Department, 1884; member of the Missouri State Medical Association; aged 76; on the staffs of the Freeman Hospital and St. John's Hospital, where he died, October 9, of heart disease.

Thomas Alva Strain, Meridian, Miss.; Chicago College of Medicine and Surgery, 1914; member of the Mississippi State Medical Association; served during the World War; aged 52; died, September 21, of hypertension and arteriosclerotic heart disease.

Henry Dundor Kunkel, Reading, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1929; on the staff of the Reading Hospital; aged 36; died, September 2, in Berlin, Germany, of complications following an operation for appendicitis.

Patrick H. Veach, Staunton, Ind.; Medical College of Indiana, Indianapolis, 1891; an Affiliate Fellow of the American Medical Association; formerly county coroner and member of the state legislature; aged 77; died, September 4, of cerebral hemorrhage.

James Benham Lucas, West Alexandria, Ohio; University College of Medicine, Richmond, Va., 1899; member of the Ohio State Medical Association; for many years member and president of the local board of education; aged 63; died, September 22.

Parish Stewart Smith, Conyers, Ga.; Atlanta College of Physicians and Surgeons, 1904; member of the Medical Association of Georgia; aged 62; died, September 7, in the Emory University Hospital of femoral hernia, acute appendicitis and peritonitis.

Roy Winton Johnson, Indianapolis; Northwestern University Medical School, Chicago, 1912; served during the World War; surgical adviser to the Aetna Casualty and Surety Company; aged 57; died suddenly, September 4, of coronary occlusion.

Henry D. Grady, Miami, Mo.; University of Missouri School of Medicine, Columbia, 1880; Bellevue Hospital Medical College, New York, 1881; an Affiliate Fellow of the American Medical Association; aged 83; died, September 2, of pyonephrosis.

Charles Russell Weaver, Twin Falls, Idaho; Harvard Medical School, Boston, 1925; served during the World War; formerly secretary of the Southside Medical Society; aged 42; died, September 7, in the Portland (Ore.) Medical Hospital of uremia.

James Horace Stimson Jr., Galveston, Texas; University of Tennessee College of Medicine, Memphis, 1938; on the staff of the U. S. Marine Hospital; aged 26; died, September 13, of inhalation pneumonia and burns received in an explosion on a launch.

Robert Milton Wolfe, South Norwalk, Conn.; Maryland Medical College, Baltimore, 1901; member of the Connecticut State Medical Society; at one time mayor; on the staff of the Norwalk Hospital; aged 62; died, September 26, in New York.

Walter Jones Adams, Norfolk, Va.; Medical College of Virginia, Richmond, 1895; an Affiliate Fellow of the American Medical Association; at one time acting assistant surgeon in the U. S. Public Health Service; aged 74; died, September 16.

Alfred Christopher Scaccia, Bound Brook, N. J.; University of Louisville (Ky.) School of Medicine, 1936; member of the Medical Society of New Jersey; aged 29; died, September 18, in the Neurological Institute, New York.

Harry Preston Pratt, Chicago; National Homeopathic Medical College, Chicago, 1892; Harvey Medical College, Chicago, 1896; Bennett College of Eclectic Medicine, Chicago, 1896; aged 79; died, September 14, of chronic myocarditis.

Joseph H. Bradfield, Atlanta, Ga.; Atlanta Medical College, 1893; member of the Medical Association of Georgia; formerly superintendent of the Battle Hill Sanatorium; aged 72; died, September 6, of arteriosclerosis and chronic myocarditis.

Leon Izgur, Brooklyn; Atlanta College of Physicians and Surgeons, 1913; member of the Medical Society of the State of New York; formerly superintendent of the Greenpoint Hospital; aged 55; died, September 27, of coronary thrombosis.

Frederick William McKenney, Brookline, Mass.; Tufts College Medical School, Boston, 1919; aged 45; on the staff of

St. Elizabeth's Hospital, Boston, where he died, September 11, of peritonitis following an operation for appendicitis.

William Feland Hickie, Kenedy, Texas; Hospital College of Medicine, Louisville, Ky., 1904; formerly city and county health officer; member of the state parole board; aged 66; died, September 23, in the Beeville (Texas) Hospital.

Manfred C. McNew, Ada, Okla.; Dallas (Texas) Medical College, 1902; member of the Oklahoma State Medical Association; aged 69; died, September 1, in Breco's Memorial Hospital of an overdose of morphine, self administered.

Allen Malone Kilgore, Los Angeles; Rush Medical College, Chicago, 1919; served during the World War; aged 47; died, September 25, in the Good Samaritan Hospital of injuries received in an automobile accident.

Oscar Rodney Emerson, Newport, Maine; Medical School of Maine, Portland, 1894; member of the board of registration of medicine; aged 67; died, September 27, of injuries received in an automobile accident.

Jefferson Davis Yates, Orange, Texas; Southern Medical College, Atlanta, Ga., 1895; county health officer; past president of the Orange County Medical Society; aged 78; died, September 25, in a local hospital of typhus fever.

Peter Charles Dodenhoff, Detroit; Michigan College of Medicine and Surgery, Detroit, 1901; for many years on the staff of St. Mary's Hospital; aged 60; died, September 23, of chronic myocarditis and arteriosclerosis.

Murray Emerson Reeder, Columbus, Ohio; Starling-Ohio Medical College, Columbus, 1910; member of the Ohio State Medical Association; served during the World War; aged 52; died, September 16, of thrombosis.

George Britton Grim, Evansville, Ind.; Kentucky School of Medicine, Louisville, 1895; member of the Indiana State Medical Association; aged 72; died, September 5, in the Methodist Hospital, Indianapolis.

Merville H. Carter, Baltimore; College of Physicians and Surgeons, Baltimore, 1878; formerly member of the board of education; aged 81; died, September 5, of cerebral hemorrhage, arteriosclerosis and hypertension.

Stoddard Sprague Martin, Windsor, Vt.; Hahnemann Medical College and Hospital of Philadelphia, 1888; served during the World War; health officer; aged 72; died, September 25, of arteriosclerotic heart disease.

Leonard J. Lunsford, Montalba, Texas; Dallas (Texas) Medical College, 1904; aged 63; died, September 10, in the Missouri Pacific Lines Hospital, Palestine, of pneumonia following injuries received in a fall.

William Powell Buck Jr., Kinder, La.; University of Louisville (Ky.) School of Medicine, 1907; member of the Louisiana State Medical Society; aged 55; died, September 27, of pulmonary tuberculosis.

John F. Cardwell, Grand Rapids, Mich.; Detroit College of Medicine, 1900; member of the Michigan State Medical Society; aged 66; died, September 24, in the Sparrow Hospital, Lansing, of heart disease.

James Edward Kelly, Jersey City, N. J.; Georgetown University School of Medicine, Washington, D. C., 1925; aged 38; died, September 3, of coronary thrombosis and cardiovascular renal sclerosis.

John Lewis Rawls, Suffolk, Va.; Jefferson Medical College of Philadelphia, 1917; on the staff of the Lakeview Hospital; aged 54; died, September 12, of injuries received in an automobile accident.

William Martin Richards, New York; Bellevue Hospital Medical College, New York, 1898; served during the World War; aged 66; died, September 11, in the Neurological Institute of cerebral embolism.

Jesse Chrisman Horton, Los Angeles; College of Physicians and Surgeons, Los Angeles, 1914; served during the World War; aged 49; died, September 24, in the U. S. Naval Hospital, San Diego.

Obed Yost, Miami Beach, Fla.; Western Reserve University Medical Department, Cleveland, 1892; formerly medical referee of the Equitable Life; aged 70; was drowned, September 27, in Biscayne Bay.

Frank Paine Ramsey, East Jordan, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; aged 66; died, September 19, of carcinomatosis.

George S. Wright, Seattle; Yale University School of Medicine, New Haven, Conn., 1884; aged 78; died, September 18, in the Providence Hospital of injuries received when struck by an automobile.

Robert Lester Paxton, Lemont, Ill.; University of Illinois College of Medicine, Chicago, 1930; member of the Illinois State Medical Society; aged 35; died, September 30, of poison, self administered.

Charles Elston Phillips * Pratt, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1905; county health officer; aged 62; died, September 11, of angina pectoris.

Jenness Morrill, Falkland, N. C.; University of Maryland School of Medicine, Baltimore, 1888; aged 74; died, September 9, of chronic endocarditis, mitral insufficiency and chronic interstitial nephritis.

Morton McTyeire Moss, Bowling Green, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; served during the World War; aged 72; died, September 3, of Parkinson's syndrome.

Frederick Irving Brown, Los Angeles; Rush Medical College, Chicago, 1890; formerly instructor in otology at his alma mater; served during the World War; aged 70; died, September 19.

Robert L. Barclay, Kennard, Texas (licensed in Texas, under the Act of 1907); aged 60; died, September 26, in the Jim Smith Memorial Hospital, Crockett, of septicemia and pneumonia.

Samuel Jackson Redman, Dexter, Maine; Medical School of Maine, Portland, 1899; member of the Maine Medical Association; aged 70; died, September 28, of carcinoma of the esophagus.

Marion Dennis Thompson * Pamplico, S. C.; Medical College of the State of South Carolina, Charleston, 1933; aged 31; died, September 28, in the McLeod Infirmary, Florence, of pneumonia.

William Herbert Aykroyd, Toronto, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1903; Manitoba Medical College, Winnipeg, Man., 1913; aged 70; died, August 29.

John J. Stoll * Chicago; Rush Medical College, Chicago, 1885; an Affiliate Fellow of the American Medical Association; aged 78; died, September 22, of uremia and chronic glomerular nephritis.

Robert Eugene Taft * Cleveland; University of Wooster Medical Department, Cleveland, 1898; aged 73; died, September 9, at Shaker Heights of coronary occlusion and diabetes mellitus.

Thomas LeRoy Jefferson, West Palm Beach, Fla.; Meharry Medical College, Nashville, Tenn., 1892; aged 72; died, September 29, in the Pine Ridge Hospital of acute appendicitis.

John McKendree Bailey, Hopewell, Va.; Medical College of Virginia, Richmond, 1924; member of the Medical Society of Virginia; aged 40; died, September 22, of cirrhosis of the liver.

William Wells Brand, Portland, Ore.; Ensworth Medical College, St. Joseph, Mo., 1899; served during the World War; aged 66; died, August 27, of arteriosclerosis and heart disease.

Patrick F. Burke, Allentown, Pa.; Jefferson Medical College of Philadelphia, 1894; aged 74; for many years on the staff of the Sacred Heart Hospital, where he died, September 3.

Roscoe Eugene Glass, Tampa, Fla.; Medical College of Virginia, Richmond, 1914; aged 52; died, September 25, in a local hospital of injuries received in an automobile accident.

Madge Dickson Mateer, Tsingtao, China; Homeopathic Hospital College, Cleveland, 1885; a retired medical missionary of the Presbyterian Church; aged 79; died, September 12.

John R. Perry, Marion, Ky.; Hospital College of Medicine, Louisville, 1907; member of the Kentucky State Medical Association; aged 55; died, September 26, of angina pectoris.

Benjamin F. Lyle, Cincinnati; Medical College of Ohio, Cincinnati, 1882; formerly member of the board of education; aged 78; died in September, at the Bethesda Hospital.

Nash Collins, Delhi, La.; Kentucky School of Medicine, Louisville, 1891; member of the Louisiana State Medical Society; aged 69; died, September 12, of myocarditis.

Lelia B. Higgins * Wilton, Maine; Woman's Medical College of Pennsylvania, Philadelphia, 1893; aged 79; died, August 1, of cerebral hemorrhage and myocarditis.

Clinton L. Montgomery, Blue Mound, Ill.; Rush Medical College, Chicago, 1895; served during the World War; aged 72; died, September 20, of coronary thrombosis.

Harvey Weston Turnipseed, Tchula, Miss.; University of Nashville (Tenn.) Medical Department, 1900; aged 68; died, September 16, in the Baptist Hospital, Jackson.

Tristram Bethea Hamer, Carrollton, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1892; aged 68; died, September 6, of cardiorenal insufficiency.

Charles Cyrus Kehl * Seattle; University of Kansas School of Medicine, Kansas City, 1920; aged 48; died, September 21, in St. Luke's Hospital of nephritis.

Isabel M. Davenport, Orlando, Fla.; Woman's Medical College, Chicago, 1891; formerly a practitioner in Chicago; aged 83; died, September 17, of heart disease.

Hiram C. Jones, Logan, W. Va.; College of Physicians and Surgeons, Baltimore, 1889; aged 78; died, September 28, in the Huntington (W. Va.) Orthopedic Hospital.

Job Nelson Statum, Birmingham, Ala.; Southern Medical College, Atlanta, 1888; served during the World War; aged 83; died, September 24, in Kessler, W. Va.

B. E. Huckabee, Birmingham, Ala.; Meharry Medical College, Nashville, Tenn., 1902; aged 75; died, September 1, of cardiac hypertrophy and chronic nephritis.

Jonathan Manning Roberts, Chicago; Columbia University College of Physicians and Surgeons, New York, 1896; aged 68; died, September 6, of chronic myocarditis.

Lewis J. Daniels, Milwaukee; Rush Medical College, Chicago, 1896; aged 65; died, September 20, at the Columbia Hospital of arteriosclerotic heart disease.

William Donaldson McNamar, Jacksonville, Fla.; Western Pennsylvania Medical College, Pittsburgh, 1892; aged 70; died, September 18, of cerebral hemorrhage.

Isaac Clark Woodford Fling, Belpre, Ohio; University of Louisville (Ky.) Medical Department, 1907; aged 62; died, September 3, of coronary thrombosis.

William C. Mack, Indianapolis; Howard University College of Medicine, Washington, D. C., 1914; aged 53; died, September 29, of pulmonary tuberculosis.

Edward Arthur Sherlock, Los Angeles; Syracuse (N. Y.) University College of Medicine, 1921; aged 44; died in September of poison, self administered.

R. S. Pounds, Redan, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912; aged 50; died in September of a self-inflicted bullet wound.

Thomas W. Henderson, Augusta, Ark. (licensed in Arkansas in 1907); aged 60; died, September 7, of chronic nephritis and cardiac hypertrophy.

George Cassell Nelson * La Harpe, Ill.; St. Louis College of Physicians and Surgeons, 1910; aged 55; died, September 21, of coronary thrombosis.

Olaf Bentzen, Miami, Fla.; Kongelige Frederiks Universitet Medisinske Fakultet, Oslo, Norway, 1893; aged 67; died, September 16, in a local hospital.

James W. Lambert, Valley Head, W. Va.; University of Louisville (Ky.) Medical Department, 1908; aged 65; died, September 4, of thrombosis.

Arthur A. McCabe, Oklahoma City; College of Physicians and Surgeons, Keokuk, Iowa, 1878; aged 83; died, September 23, of cerebral hemorrhage.

Thomas J. Hackett, Houston, Texas; Meharry Medical College, Nashville, Tenn., 1913; aged 48; died, September 9, of acute glomerular nephritis.

Charles Henry Phillips Jr., St. Louis; Meharry Medical College, Nashville, Tenn., 1908; aged 57; died, September 29, of hypertensive heart disease.

Jacob Shrader Smith, Bellingham, Wash.; Louisville (Ky.) Medical College, 1898; served during the World War; aged 63; died, September 14.

Morris Schaner * Toledo, Ohio; University of Cincinnati College of Medicine, 1916; aged 50; died, September 28, of acute dilatation of the heart.

James Elliott Blakemore, Van Buren, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1892; aged 76; died, September 14.

Mary Roush Krieger, Cincinnati; American Eclectic Medical College, Cincinnati, 1891; aged 91; died, September 14, in the Bethesda Hospital.

Elmore Estes, Johnson City, Tenn.; Vanderbilt University School of Medicine, Nashville, 1911; aged 61; died, September 28, in a local hospital.

Bureau of Investigation

THE MME. ADELE FRAUD

The Interesting History of Adele Millar's Quackeries

On Jan. 24, 1939, the United States mails were closed to Adele Millar, Adele Millar Prentiss and Francisca of Los Angeles and San Francisco. The case illustrates once more the futility of temporizing with quackery. The story that follows is based on (1) material in the files of the Bureau of Investigation of the American Medical Association, (2) information supplied by the Post Office Department and (3) facts released by the Federal Trade Commission.

The first record that the Bureau of Investigation has of any one known as Adele Millar appears in a clipping from the San Francisco Call of July 30, 1911. This was a column-long story of the case of a girl who, according to her friends, "was the unwitting victim of inept and bungling" work of a "beauty specialist" concern. The girl—a suicide—the story stated, was abnormally sensitive about her complexion. She went to a physician who refused to do what she asked because of the danger involved in the treatment she desired. She then went, according to the newspaper report, to the Millar Institute, whose proprietor was an Adele Millar. The result of the "treatment" she received so blotched and scarred the girl's face that she disappeared; her body was found later "cast up by the waves at Bolinas beach."

The newspaper story further stated that, coincidentally with the girl's disappearance, Adele Millar's husband gave out that his wife "had gone to Europe for an indefinite stay." The paper, on investigating, reported that the facts were that this Adele Millar had not left the state but was "sojourning incognito at a chicken ranch on the Mountain View road one mile from Petaluma." The paper added: "Her [Adele Millar's] departure for 'Europe' occurred simultaneously with the announcement of the girl's disappearance." The Bureau of Investigation has no record that any action was taken in this case.

The second record that the Bureau of Investigation has of a person of this name was a report from the Board of Medical Examiners of California stating that an Adele Millar was arrested on July 21, 1927, charged with violation of the Medical Practice Act of California. She was arraigned in Division 6, Municipal Court of Los Angeles. She pleaded guilty and was sentenced to pay a fine of \$100 or serve fifty days in the city jail. *Sentence was suspended* for two years on condition that she would not violate the State Medical Practice Act during that period.

The third record came about three years later, when Adele Millar was again arrested and arraigned on April 15, 1930, in the same court as before (Division 6, Municipal Court of Los Angeles), charged once more with violation of the Medical Practice Act. Again she pleaded guilty and was sentenced to serve sixty days in the city jail. But *sentence was suspended* for 180 days on condition that she acquaint herself with the law pertaining to her work!

The fourth record came about four years later, when a Post Office fraud order was issued Jan. 4, 1934, closing the mails to "Mme. Adele," of Los Angeles, a trade name used by Adele Millar. At this time she was selling a "Wonder Peel Paste" which she had been advertising four years previously and which contained caustics. Although she represented that her paste was harmless, the Post Office report stated that "expert medical evidence shows that the burning caused by its use is extremely dangerous and complaints in evidence show two actual instances in which death was narrowly averted as a result of such burns." In addition, Adele Millar sold "Beauty Turtle Oil," a "Developing Cream" and a so-called "Skin Tightener"—the usual armamentarium of the beauty-specialist quack. Because these were sold through the mails under fraudulent claims, the fraud order was issued. The Post Office also obtained an indictment against Adele Millar, charging her

with using the mails to defraud. She pleaded guilty and was given a *suspended sentence* of two years!

The fifth record is contained in a release issued by another government agency, the Federal Trade Commission, on March 7, 1938—about four years after the first fraud order was issued. The release read in part:

"The Federal Trade Commission has issued a complaint charging Adele Millar, 177 Post St., San Francisco, with misrepresenting the therapeutic value and merit of Wonder Peel Paste, advertised as a treatment for skin ailments and sold in interstate commerce. The respondent trades as Mme. Adele and Chez Adele."

The conclusion of the Commission's case was reported in a release it issued on July 29, 1939, reading as follows:

"The Federal Trade Commission ordered Adele Millar, trading as Mme. Adele and Chez Adele, San Francisco, to discontinue false representations in the sale and distribution of a cosmetic preparation designated "Wonder Peel Paste," or any other similar preparation.

"Under the order, the respondent is prohibited from representing that her preparation will withdraw toxins from the skin, accelerate chemical

changes in the living skin cells, or supply materials to the skin to repair waste tissues; that its use will prevent or remove freckles, liver spots or wrinkles; that it will prevent or remove or have any beneficial effect in aiding in the removal of, any blemishes or other conditions of the skin which are due to or persist because of a systemic or metabolic disorder or condition; that it will prevent pimples, blackheads, puffs, scars, pits, acne or crepey neck, and that it has any beneficial effect in aiding in the removal of pimples, blackheads, puffs, scars, pits, acne or crepey neck, unless such representation is limited to those conditions which are of a surface character only.

"The respondent, now known as Adele Millar Prentiss, is also ordered to cease representing that her preparation has any beneficial effect on the metabolism or nutrition of the tissues."

The action of the Post Office Department referred to in the first paragraph of this article, closing the mails to Adele Millar, Adele Millar Prentiss and Francisca, was due to her having resumed, under these names, the mail-order sale of her Wonder Peel Paste in defiance of the original fraud order issued against her in 1934. This necessitated the issuance of the supplemental fraud order of January 1939 against the later trade names used by Adele Millar and brings the record of this

individual up to date. All of this must be very amusing to the Adele Millar organization. Certainly it reveals the inability of the authorities concerned to inhibit her activities. The long time which usually passes before the issuing of final orders by federal organizations gives many a promotor opportunity to reap the field before the storm breaks.

Correspondence

"OBSTETRIC SHOCK"

To the Editor:—Dr. Virgil H. Moon has called my attention to the fact that material from his book ("Shock and Related Capillary Phenomena," New York, Oxford University Press, 1938) was used in my article "Obstetric Shock: Its Causes, Recognition and Management" (THE JOURNAL, September 23, p. 1183) without due credit being given him. On comparison, to my utter chagrin, I find that Dr. Moon's statement is correct and I am therefore anxious to make amends for this error.

After spending some six or seven months reviewing the general subject of shock, including the few existing articles on obstetric shock, I began to write a paper in the form of an editorial for a chairman's address. Such an article could consist only of a review of the literature, with some practical considerations gleaned from a personal experience of some ten years' interest in the subject. It was a most difficult job, owing largely to the confused state of the vast literature on shock. Work piled up; "time marched on," and I deemed it necessary to obtain the assistance of a ghost writer, to whom I gave all my notes (a voluminous quantity), including an extensive bibliography and a partly written address. In due time he returned the completed article. It did not occur to me to check meticulously every statement as to authorship. I had full confidence that credit would be given wherever necessary for material used. It was not until I received Dr. Moon's letter that I appreciated the fact that my ghost writer had taken many paragraphs in toto from the final chapter of Dr. Moon's monograph, published by the Oxford University Press.

For this error of omission I offer my sincere apology to Dr. Moon and to the Oxford University Press.

HARVEY B. MATTHEWS, M.D., Brooklyn.

THE THECA INTERNA CONE: A TEST FOR FOLLICULAR GROWTH AND STIMULATION

To the Editor:—During the meeting of the American Medical Association in St. Louis and since then in meetings of medical societies all over the country, a moving picture has been shown which deals with a new gonadotropic substance recovered from the serum of pregnant mares. In this picture the development of the growing graafian follicle is shown. This part includes the "Theca Interna Cone," giving the name as such but not that of the author.

The author's name is of little importance as soon as the discovery is generally acknowledged. Until this stage is reached, the author's name should be mentioned in moving pictures, as is customary in other forms of medical publication.

My papers dealing with the growth of the graafian follicle and the causes of its ascent to the ovarian surface cover a period of sixteen years of histologic research. The pathologist Prof. Ludwig Aschoff, whose assistant I was from 1921 to 1922, told me to find out why the follicle ruptures. He anticipated that, in addition to the endocrine stimulus, there was a special anatomic mechanism, because other pathologic cystic formations of the ovary almost never rupture even when they reach the size of a man's head.

In my first paper (Why Does the Follicle Rupture? *Arch. f. Gynäk.* 119:168 [Sept.] 1923) it was shown that the dis-

tance between the follicle and the ovarian surface in human beings becomes smaller with the appearance and development of the thecal layers. At the same time it was found that there exists always an eccentric type of growing in follicles, while pathologic cystomas have a concentric way of growing. A one-sided thickness of the theca interna, rich in cells, toward the ovarian surface is present, which in larger follicles is from eight to ten times wider at the upper pole than at the lower pole toward the hilus. The theca externa, on the other hand, rich in connective tissue fibers, stays thick around the lower hemisphere and becomes thin at the upper hemisphere toward the ovarian surface, thus keeping the follicle like a goblet from expanding to any other side but the surface of the ovary. The active growth of the theca interna, which is soft, owing to its richness in fast multiplying cells, provides an area of lower resistance in direction toward the cortex and albuginea.

In a later study (Theca-Interna Cone, the Pathmaker of the Follicle, *ibid.* 158:628, 1934) it was demonstrated in human and cat ovaries that there was not only a blunt one-sided thickness of the theca interna but a wedgelike theca interna cone with a triangular outline which always points toward the nearest part of the ovarian surface. This thecal cone possesses a tropism toward the surface like the sprout of any seed and plows the path for the follicle by active infiltrating growth through the stroma and the albuginea. The follicle proper follows the line of least resistance thus provided, passively adopting frequently an elliptic or even a cone shape itself.

The theca interna cone can be demonstrated only in serial sections, perpendicular to the ovarian surface, running through the apex of the cone, as geometric considerations easily show. This must have been the reason why it has not been found before in an organ thoroughly examined by many authors for more than a hundred years.

In order to make sure that the theca interna cone was part of the normal histologic and physiologic picture of the ovary, it was necessary to prove its presence in as many mammalian species and orders as possible. This was done together with Erika von Moellendorff (The Theca Interna Cone, a Typical Structure in Growing Mammalian Follicles, *ibid.* 160:278, 1935). The theca cone could be verified in all mammalian species the ovaries of which we were able to obtain during the estrus and preestrus. In addition to *Homo sapiens* and cats, the thecal cone was found in horses, cows, swine, dogs and rabbits.

The work was completed at the Mayo Foundation and a final report, based on more than 18,000 microscopic slides, given before the staff of the Mayo Clinic (The Theca Interna Cone and Its Role in Ovulation, *Surg., Gynec. & Obst.* 67: 299 [Sept.] 1938; abstr., *Proc. Staff Meet., Mayo Clin.* 13: 443 [July 13] 1938).

The theca interna cone is found only in growing follicles. It disappears when degeneration sets in. It therefore can be used as a test for normal follicular growth and stimulation.

ERWIN O. STRASSMANN, M.D., Houston, Texas.

RABIES

To the Editor:—The report on "Rabies in Birmingham, Alabama" (Drs. G. A. Denison and J. D. Dowling, *The Journal*, July 29, p. 390) raises several questions that call for further discussion. No one should find fault with the statements of fact in their report; but it is unfortunate that some of the conclusions that they drew were published, because these have already been seized on by enemies of public health work and orthodox medical practice to cast discredit on even such rabies control measures as Drs. Denison and Dowling themselves advocate.

The authors' thesis is stated in the first paragraph of their report: "We are especially concerned with those problems

which confront the physician; namely, the value of antirabies vaccine and indication for its administration." Their intimation that "failure to control the dog" is what calls for other antirabies measures is one with which there is or should be general agreement. The factors that they mention as leading to the "indiscriminate administration of vaccine," as given in the third paragraph of their report, may also be largely accepted as widely prevalent, though the indictment suggested by the word "indiscriminate" is much too strong.

Since the thesis stresses the "problems which confront the physician," it seems strange that in the fourth paragraph of the report the prospective patient is described as being in a state of "such extreme mental anguish that nothing short of vaccine treatment can prevent nervous collapse of the individual"; and yet they go on to say that "the physician too often fails to maintain a professional attitude and allows himself to be influenced by the undue apprehension of the patient." It will surely be agreed that the public should be educated as rapidly as possible so that "undue apprehension" will more and more rarely occur, but this takes a long time, and the health officer or practicing physician who is confronted with an individual so extremely apprehensive as to be in danger of nervous collapse ought seriously to question his own wisdom and "professional attitude" if he refuses to give vaccine. Such persons very often truly believe and violently feel that it is the duty of the health department to give them the vaccine, and refusal to give it leads to loud criticism freely voiced among friends and neighbors. Facing such a situation, the health officer would injure his department vastly more in the mind of the public than he could possibly gain in any way by refusing the treatment. What the influence of such an attitude on the part of a practicing physician would be on his practice is left to the physician to judge.

As to statistical data given in the report, no question is raised; but one obvious conclusion regarding the effectiveness of canine vaccination was not drawn. If the incidence of rabies among all dogs belonging to white owners was 1.5 per cent, while the incidence among vaccinated dogs (40 per cent of the whole group) belonging to white owners was 0.5 per cent, this would indicate that about 75 per cent of vaccinated dogs were protected by the treatment.

The mortality of 0.06 per cent among 42,947 persons who received antirabies vaccine may be compared with the average mortality figure of 0.36 per cent given in League of Nations data concerning persons treated after being bitten by known rabid animals. The authors do not state the proportion of the 42,947 persons who are known to have been bitten by rabid dogs, but if it was only one in six their data would be as good evidence for the use of antirabies vaccine as are the League of Nations data.

It is difficult to see how the conclusion "The persistence with which fatalities continue to be equally distributed among the treated and untreated" can be drawn from the fact that twenty-three of the forty-eight fatal cases had received supposedly adequate treatment. Such a conclusion could logically follow only if the number of untreated persons bitten by known rabid animals was approximately equal to the number of treated persons known to have been so bitten. No definite data are given to substantiate any such assumption. Such data should not be hard to collect if they exist, for while it is never possible to obtain reports of all dog bites it is always possible to trace what happens to those people who refuse treatment after it is found that they have been bitten by known rabid dogs, which class after all is the criterion of susceptibility to rabies.

The argument based on the comparative number of deaths among Negroes and white persons from some points of view has some weight, but even here there are other variable factors that have not been taken into consideration. For instance, the

statement that "Negroes undoubtedly are bitten and otherwise exposed to rabies as often as the white persons" is an assumption not susceptible of proof from the data given; the very fact that "their animals are subject to the poorest of care" would leave the Negroes' dogs in most instances free to follow the frequently observed tendency of a rabid dog to run away from home and bite other dogs, while the well cared for dog belonging to the white family would be much more likely to be observed and handled in the early stages of the disease, resulting in bites of the owner or members of his family. It is in "caring for" his dog that the owner of a rabid animal is most often bitten.

It is claimed, therefore, that the following quoted statement is seriously open to question: "In the experiences cited there is little relation between mortality from rabies and the administration of antirabies vaccine, for (1) among the highly exposed untreated (Negro) population fatalities are no greater than among the highly exposed treated (white) population, and (2) such rare fatalities as do occur are equally distributed among the treated and the untreated."

If the authors really believe this twofold assertion, it is difficult to see why they advocate giving antirabies vaccine at all. It is indeed surprising to read through the rest of their report and find them recommending a rabies control program practically identical with that in effect in other parts of the country where rabies is a problem and to note that in Birmingham in 1938 the ratio of antirabies treatments to the number of known rabid animals was 2.9. In Los Angeles County, another rabies focus, this ratio was less than 2.0.

Some further Los Angeles County data on cases of human rabies may be of interest. In this county it is not often that a person refuses treatment after it is found that he has been bitten by a rabid dog, and the force of pound men and quarantine officers on the job do not fall far short of finding all dogs that become rabid and tracing all persons bitten by them. In a recent two year period there were five deaths from human rabies. In three of the five cases treatment was neglected, one reason being that two of the bites were not reported till the persons became ill. One of the dogs concerned was a pup which was killed by its owner after it had bitten his child. Another was not known to have bitten any other person and was never found. One bite was recognized soon after it occurred, but the person bitten was intoxicated and careless and did not heed the health department's counsel to take antirabies vaccine. In the fourth case the treatment could not be considered adequate in view of the location and type of the bite. In the fifth an adequate dosage of vaccine was given, but it was vaccine of local manufacture and not generally approved.

In passing, it should be noted that as yet no standard method of determining the potency of antirabies vaccine on the market is in effect. This defect in procedure is one that should be remedied, and until it is one may expect too frequent failures of the vaccine to protect. Even when all possible tests are made, however, we do not yet have a perfect vaccine for any disease; but this is not considered a valid argument against using vaccines.

All should certainly agree with the authors' first sentence in their conclusion: "The data presented are not of a type to warrant definite conclusions." It is to be regretted that they apparently came near reaching such conclusions, or at least expressed themselves in such a way as to put unwarranted weapons into the hands of people who delight in attacking health officers and the public health program.

J. L. POMEROY, M.D.

H. O. SWARTOUT, M.D., DR.P.H.

Los Angeles.

County Health Officer and Director of the Bureau
of Communicable Disease Control, respectively.

ALLERGY TO COLD

To the Editor:—A woman aged 53 had a hysterectomy and roentgen therapy following a diagnosis of carcinoma of the cervix nine years ago. Physical examination reveals obesity, apparently from a familial trend, and blood pressure of 180 systolic and 110 diastolic but otherwise essentially normal conditions. The urine is normal and the hemoglobin is 70 per cent. She is highly nervous and requires phenobarbital to sleep. On Aug. 13, 1939, she was washing cucumbers in cold water and developed, after about ten minutes' exposure, a diffuse swelling of the hands accompanied by itching and burning. This was relieved by the injection of 0.5 cc. of a solution of epinephrine hydrochloride. On August 15, while standing outdoors in a sleeveless dress in a cool wind, she felt on itching of the flexor surfaces of the forearms and presently developed urticarial wheals in these areas. At a later date the ingestion of an ice cream cone caused gross rapid edema of the upper lip and tongue, as did contact with ice cubes in an iced drink. The application of an ice bag for nosebleed caused, in twenty minutes, edema of the eyelids and forehead to the extent that she could not open her eyes. This edema responds to epinephrine and ephedrine but the injection is followed by severe headache, presumably due to the hypertension. There is no history, either personal or familial, of allergy of any type prior to August 13. Could you offer me any suggestions or literature as to the management of such a case during the coming winter months? Her financial status would prevent the patient's removal to a warmer climate. A. H. Field, M.D., Randolph, Minn.

ANSWER.—This is an undoubted case of hypersensitiveness to cold. In addition, another type of allergy (such as food allergy) may be present. Several methods have been employed in the treatment of cold allergy. One consists simply of systematic exposure to low temperatures in order to build up tolerance. This may be accomplished by daily cold showers or baths followed by a warm shower if the reaction is undesirable. A brisk ice rub followed by treatment with a heat lamp is recommended by some (Duke, W. W.: *Physical Allergy as a Cause of Dermatoses*, *Arch. Dermat. & Syph.* 13:176 [Feb.] 1926). Another method of exposure to cold is advised by B. T. Horton and G. M. Roth (Collapse While Swimming: The Most Dangerous Consequence of Hypersensitiveness to Cold, *Proc. Staff Meet., Mayo Clin.* 12:7 [Jan. 6] 1937). It consists of immersion of a hand in water at 10 C. for one to two minutes twice daily for three or four weeks. However, this method is probably more useful in the type of cold hypersensitiveness in which constitutional histamine-like effects are prominent.

In recent years considerable attention has been given to the relationship of histamine to allergy and particularly to cold hypersensitiveness. Treatment with histamine has been recommended on the basis that the reaction phenomenon will be exhausted. Thus, G. W. Bray (A Case of Physical Allergy: A Localized and Generalized Allergic Type of Reaction to Cold, *J. Allergy* 3:367 [May] 1932) cited a case of cold allergy in a boy who was relieved by daily histamine injections beginning with 0.1 mg. and increasing to 1 mg. It is felt, however, that these doses are excessive. Horton and Roth recommended injections of histamine in doses of 0.1 mg. or less twice daily for two to three weeks.

More recently (Roth, G. M., and Horton, B. T.: Hypersensitiveness to Cold; Treatment with Histamine and Histaminase: Report of Case, *Proc. Staff Meet., Mayo Clin.* 12:129 [March 3] 1937) histaminase has been used in the treatment of cold hypersensitiveness. A dose of from 5 to 10 units three times daily, taken by mouth, is the usual procedure. The function of the histaminase is to detoxicate the excess of histamine formed in the tissues.

TUBERCULIN TREATMENT FOR TUBERCULIDS

To the Editor:—Will you please tell me the exact method of administering old tuberculin in the treatment of rosacea-like tuberculid (Lewandowsky)? I wish to start with a 1:10,000,000 dilution. M.D., New York.

ANSWER.—"Exact" is not an appropriate term for tuberculin therapy, for each physician has his own technic and each patient reacts in a different way and must be managed differently. Most users of tuberculin therapy test the sensitivity of the patient by the Mantoux intracutaneous test and begin treatment with a subcutaneous injection of an amount slightly less than that producing a reaction. Once or twice a week this dose is repeated for a few times; then, if no reaction has been caused, the amount of tuberculin is increased cautiously and

this dose is repeated several times. From 10 to 100 per cent increase is made depending on the physician's judgment of the patient's tolerance.

The patient, if ambulatory, is instructed to take his temperature three times daily and to record it and any symptom that he may notice. At the interview with his physician these data are discussed and evaluated.

It is the present practice to use sterile physiologic solution of sodium chloride for diluting tuberculin, without the addition of phenol. If sterile, the dilutions keep their strength for some time. Great care must be used in cleansing the implements in which tuberculin has been used, for a minute amount of one of the stronger solutions can alter the dose of a weak solution materially. Many workers keep special syringes and needles for the dilute solutions. These are cleansed and boiled in distilled water.

H. S. Burnell-Jones (Tuberculin in the Treatment of Cutaneous Disorders, *Brit. M. J.* 1:1212 [June 15] 1935) advises two doses a week for the first few weeks, then one a week, increasing 10 per cent when there has been no reaction. He depends on a general reaction, counting a rise of temperature to 99 F. as such. He does not approve local reactions and in order to avoid them he injects between the shoulders, where the skin is less liable than that of the arm or leg to give local reaction. He places great value on a rest period of from six to eight weeks now and then during a course of treatment, which he thinks gives the tissue cells a chance to recuperate from the repeated stimulation of tuberculin.

Other measures to increase the patient's resistance and to facilitate local healing must not be neglected. In fact, many authorities consider tuberculin an adjuvant to other therapeutic measures rather than the chief factor. For the tuberculin treatment the motto must be "Make haste slowly."

BUTADIENE, ISOPRENE AND PIPERYLENE

To the Editor:—Will you please inform me of any possible dangers of both acute and chronic forms to dolly exposure to the following volatile hydrocarbons: butadiene, isoprene, piperylene. The patient uses no masks and has come in contact with concentrated vapors of the gases for the past two years but to date has noticed only nausea after exposure.

Leon Miller, M.D., Philadelphia.

ANSWER.—At this time these chemicals are used principally in the production of plastics, synthetic rubber and rubber-like substances. The destructive distillation of natural rubber yields some isoprene. Conversely, the polymerization of isoprene may lead to a product resembling natural rubber. Butadiene, when polymerized, may furnish "Buna" rubber, likewise resembling natural rubber. All of these substances, as a result of fairly simple chemical or physical manipulations, furnish a wide variety of new compounds not all of which can be predicted. If isoprene is merely allowed to stand for a few weeks, new physical properties may arise. In the freshly prepared state, none of these three mentioned chemicals are highly toxic. All are mild narcotics. All are irritants to the mucous membranes. Such actions are acute. By way of chronic changes, emphysema may be produced. Larionov and his co-workers (*Kozanskiy med. zhur.* 30:440, 1934) found that the minimal lethal dose of butadiene for mice through the inhalation of vapors is from 200 to 300 mg. per liter of air. For isoprene, the corresponding killing dose is 140 mg. At autopsy, pathologic change was limited to the respiratory tract; no changes were associated with the heart, liver or kidneys. The physiologic properties of the polymers and compounds of these substances are little known except in the case of chlorinated butadiene (chloroprene). Von Oettingen and associates (*J. Indust. Hyg. & Toxicol.* 18:240 [April] 1936) reported toxic action of chloroprene when administered to laboratory animals. Of their subcutaneous series they stated: "The smallest dose which could be administered was 0.001 cc. per gram and this killed 100 per cent of the animals within three and one-half to four and one-half hours." By inhalation, as little as 0.3 mg. per liter was injurious. The pathologic features disclosed included pulmonary irritation, pulmonary edema, cardiac impairment, dilated visceral blood vessels, gastro-enteritis, nephritis, cutaneous irritation and loss of hair. These severe manifestations are to be associated with the introduction of the chlorine ion rather than with the butadiene nucleus itself, since the earlier cited data indicate a far lower toxicity for the unchlorinated substance.

While it is possible to rate the substances mentioned in the query as of a comparatively low order of toxicity, they are not wholly inert and the guiding data are meager. For the time being, at least, exposure to high concentrations of vapors should be avoided.

QUERIES AND MINOR NOTES

1901

DIFFERENTIAL DIAGNOSIS OF ASCITES

To the Editor:—A 34 year old colored man, apparently in good health, bent down while working and when he suddenly straightened up felt "something snap" in his abdomen in the midline below the umbilicus. There was no pain. About six hours later his abdomen was distended, and it remained so for three months, till operation, except for some lessening of distention by the use of salyrgan. There was some pain in the right lower quadrant, the cause of which was diagnosed in office fluoroscopy as a ruptured muscle. His only other symptoms were some frequency and urgency. Physical examination showed negative except for rounded abdomen, which had all the characteristics of ascites. There were a positive Wassermann reaction, negative spinal fluid examination and negative blood count and blood chemistry; gastric analysis showed free hydrochloric acid of 50 and total acidity of 63; urinalysis showed occasional pus cells; x-ray examination showed all organs to be in good condition and an extraordinarily well developed abdominal musculature. There was no mention of the fluid withdrawn, and a tentative diagnosis of tuberculous peritonitis and syphilitic crisis was made. Can you tell me what relationship there could be between the "injury" and the sudden development of ascites? Is there such an entity as syphilitic peritonitis? Could the syphilis have been aggravated to cause ascites by virtue of hepatic cirrhosis? Can you give me any other possible diagnosis?

ANSWER.—This question involves the differential diagnosis of ascites. It is assumed that the exploratory laparotomy demonstrated that the distention was due to ascites, although the question does not so state. Among the common causes of ascites are circulatory disturbances, renal disease, hepatic obstruction, leukemia, Hodgkin's disease, neoplasm and tuberculous. Syphilis as a rule causes ascites only by producing a perilepatitis or other hepatic obstruction. This and hepatic obstruction for other causes seem ruled out by the statement that "exploratory operation showed all organs to be in good condition." The same statement fairly well rules out abdominal neoplasm with ascites. Circulatory failure is incompatible with the history, and renal or blood disease does not fit in with the laboratory observations. Hodgkin's disease seems unlikely but should be kept in mind.

To correlate the sudden appearance of ascites with the injury is a difficult problem. It must be remembered that from 1.5 to 2 liters of fluid may be present in the peritoneal cavity without physical signs and that from 4 to 5 liters will cause no great distention. It is difficult to imagine what sort of "injury" could cause the accumulation of more than 5 liters of fluid within six hours and leave no traces that could be found at exploratory laparotomy three months later. It seems much more likely that fluid was already present in the abdomen at the time of the "injury." Indeed, the sensation that "something snapped" may have been a sudden shift of the fluid from one portion of the abdomen to another. Tuberculous peritonitis seems to be the most likely diagnosis. An x-ray examination to investigate the possibility of pulmonary tuberculosis would be helpful. The injection of some of the fluid into a guinea pig might easily settle the question.

TOPICAL ANESTHETICS

To the Editor:—Will you kindly send me information concerning so-called topical anesthetics? I have read conflicting statements concerning ethyl aminobenzoate U. S. P. (benzocaine), for example, as to its efficacy in relieving painful superficial burns. There are several preparations which are claimed to have a local anesthetic effect in the relief of superficial burns and localized pruritus. Which of the anesthetics used are most effective on cutaneous surfaces, and are these absolutely nontoxic and safe to use over a large area, even in young children?

M.D., New York.

ANSWER.—There is no absolutely nontoxic and safe topical anesthetic. Ethyl aminobenzoate (benzocaine) was discovered before orthoform but did not come into prominence until the dangers inherent in the use of orthoform had become known. L. Schwarzschild (Sensibilisierungs Versuche aus der Orthoform Reihe, *Arch. f. Dermat. u. Syph.* 156:432, 1928) reported two cases of severe dermatitis due to ethyl aminobenzoate (anesthetin) in 1928. His study of the sensitizations produced by members of this group of drugs convinced him that these effects were caused by certain chemical subgroups. M. H. Goodman (Cutaneous Hypersensitivity to the Procaine Anesthetics, *J. Invest. Dermat.* 2:53 [April] 1939), as a result of his recent investigations, comes to the same conclusion. Butesin picrate in ointment form is widely used in the treatment of burns and is a common cause of dermatitis which may become much more disabling than the original burn is not the only harm that such drugs may do. Bernard Fantus and H. A. Dyniewicz (Compound Solution of Tannic Acid, *THE JOURNAL*, July 17, 1937, p. 200) warn against the use of the tannic acid treatment for small burns because of the damage done to skin

cells and the resultant delay in healing. They state that the tannic acid method is applicable only to large burns that threaten serious systemic effects. The soothing effect of protection from the air, such as can be produced by covering the area with melted sterile paraffin, is usually sufficient without the use of local anesthetics. If not, it may be preferable to use a general sedative rather than a local one.

Most of the topical anesthetics are effective only on surfaces from which the epithelium has been removed. Béla Freystadt (Experimenteller Nachweis der Penetrationsfähigkeit einiger Oberflächenanästhetika durch die unverschrte Haut, *Dermat. Wchnschr.* 106:73 [Jan. 15] 1938) after extensive experimentation found that pantocain in ointment will penetrate the unbroken skin and cause anesthesia, but only after hours of application. He also found that the repeated use of these ointments caused dermatitis. Phenol in 2 per cent water solution for cold but only slightly for touch and having no effect on the feeling for pain or warmth. Solutions of phenol in alcohol, glycerin or oil were much less effective. Tricresol, a 2.5 per cent solution in water, was less active than the phenol solution in water, and 10 per cent alcoholic solution of beta-naphthol, salicylic acid, guaiacol and resorcin had less effect, decreasing in the order in which they are named. Since phenol, even 1.5 per cent watery solution applied as a wet dressing, is credited with causing gangrene, most dermatologists do not use it any stronger than 0.5 per cent in water and 1 per cent in the other solvents. Sensitization to phenol is much less common than is that to the more complex drugs previously discussed.

DIAGNOSIS AND TREATMENT OF NERVE INJURY

To the Editor:—I have a case of radial and ulnar nerve injury of the left forearm and hand region with what is apparently physiologic solution of continuity without anatomic interruption of the nerve pathways. It is desirable to study the reaction of degeneration in the involved muscles in order to throw light both on exact diagnosis and on prognosis. Please comment on the efficacy of electrical stimulation of the involved muscles of the forearm as a therapeutic measure. Can you advise me concerning the purchase of an apparatus which will supply galvanic and faradic current and cathode and anode opening and closing currents?

M.D., Ohio.

ANSWER.—In the study of paralyzed muscles one requires only a source of galvanic and faradic currents. Such an apparatus can be purchased from several firms which deal in electrical supplies. If the nerve is completely degenerated, one will obtain no reaction to faradism from the nerve or muscle, and the galvanic reaction of the muscle will be slow and well sustained. If there is no degeneration of the nerve, both faradic and galvanic stimuli will give prompt contraction when applied to the muscle and to the nerve. If the nerve is not degenerated, one expects a prompt and complete recovery in most cases. If it is degenerated, improvement will be slower and usually stops short of complete recovery, since many regenerating axons go astray and exercise no useful function. Electrical stimulation has little if any therapeutic value in cases of peripheral nerve paralysis. Denervated muscles should be placed at rest in splints in such a position as to secure relaxation. Stretching and probably contraction of denervated muscles cause serious injury to the muscle fibers and at least delay recovery. The principles of treatment are identical with those employed in the treatment of cases of infantile paralysis.

LACQUER THINNERS

To the Editor:—I should appreciate information concerning the ingredients of and the toxicity of "Qualolac Thinner No. 631." This product is manufactured by the Qualolac Products, Inc., 21 Gay Street, New York City. It is used as a varnish thinner by furniture manufacturers.

M.D., New Jersey

ANSWER.—At the present time, two types of thinners enjoy wide use for general coating purposes. The best thinners consist chiefly of toluene or xylene or mixtures of the two, together with either hydrogenated naphthas or natural petroleum fractions closely similar to the hydrogenated naphthas. A second class of thinners, and that most likely to be used with lacquers and on most furniture, contains in addition to the substances mentioned such materials as butyl acetate, isopropyl acetate, butyl alcohol, ethyl alcohol or closely related substances in the same series. In addition, special thinners may contain small quantities of antiblooming agents, turpentine, benzene and the like. These statements, both as to constituents and toxicity, apply to thinners in general and to no specific product. All these substances possess some degree of toxicity. Benzene, if present, is the most toxic of the possibilities mentioned.

Toluene is less dangerous than benzene, but this is due partly to its higher boiling point. Butyl alcohol is more dangerous than ethyl alcohol, although the ethyl alcohol may be denatured with 5 per cent methyl alcohol. Full information does not exist with regard to the toxicity of hydrogenated naphtha, and at the present time it is customarily classed as of the same order of toxicity as petroleum naphtha. Some claims have been made that hydrogenated naphtha may contain up to 18 per cent of cyclic compounds. To the extent that this is true, hydrogenated naphtha is to be respected more than naphtha. The acetates represent the constituents of least toxicity but are capable nevertheless of inducing mild conjunctivitis, respiratory irritation and similar abnormality. Thinners of almost any type are capable of inducing dermatitis, either through direct irritation or fat removal. It is always desirable that no workroom atmosphere contain high concentrations of the vapors of thinners. In coating operations, exhaust systems are customarily desirable or necessary, and in addition in some workplaces respirators or helmets may be found in use.

SULFANILAMIDE, NICOTINIC ACID AND METHYLENE BLUE

To the Editor:—My experience with the use of large doses of sulfanilamide is confined principally to the treatment of gonorrhea. Some of my patients have complained of shortness of breath on exertion (due to methemoglobinemia?). Hartmann advises from 1 to 2 grain (0.065 to 0.13 Gm.) doses of methylene blue every fourth hour for the prevention of methemoglobinemia. Not all observers agree that cyanosis and methemoglobinemia are associated; in addition, methylene blue tends to cause nausea but may be given in enteric coated capsules. There are also a few observers who do not believe that sodium bicarbonate is necessary. Finally nicotinic acid seems to be of distinct value. At this rate I would want to give my patients (a) sulfanilamide, (b) nicotinic acid, (c) sodium bicarbonate and (d) methylene blue. If such a scheme is followed, would it be desirable from the standpoint of possible incompatibility to space these drugs, say, one drug every hour; or is there no incompatibility?

M.D., Pennsylvania.

ANSWER.—No evidence is available on which to base an opinion as to whether or not incompatibility would develop from the simultaneous administration of sulfanilamide, nicotinic acid, sodium bicarbonate and methylene blue. In considering the combination of sulfanilamide and methylene blue it might be well to review the work which has been done on relieving cyanotic symptoms originating from sulfanilamide therapy by methylene blue (*J. Clin. Investigation* 17:699 [Nov.] 1938; 18:179 [March] 1939). The rationality of adding nicotinic acid and sodium bicarbonate at the same time is not experimentally and clinically established. It would seem better that the drugs, if indicated, be given concurrently.

DEATH OF EPILEPTIC PATIENT FROM LOCAL ANESTHESIA

To the Editor:—A white man aged 32, in excellent physical condition with the exception of existing epilepsy, was prepared for a hemorrhoidectomy. The surgeon used what he considered 1½ ounces of 2 per cent procaine hydrochloride prepared by a graduate nurse. One cc. of a solution of epinephrine hydrochloride was added to the procaine hydrochloride before infiltration of the hemorrhoidal area. Just as the surgeon commenced to remove the first hemorrhoid, the patient complained of nervousness, developed a horizontal nystagmus, had five convulsions (clonic type) one after the other and died on the table. The cause was considered respiratory, the breath becoming progressively weaker in spite of the use of artificial respiration. The patient was treated with phenobarbital, receiving one 1½ grain (0.1 Gm.) tablet daily, and had on an average from two to five seizures a month but never status epilepticus. The head and upper extremities were violaceous after death. Investigation revealed that the nurse had made up 45 cc. of 2 per cent pontocaine hydrochloride solution in place of 2 per cent procaine hydrochloride, and this was used for infiltration. Would you consider the pontocaine hydrochloride the primary cause of death?

M.D.

ANSWER.—The symptoms preceding death are characteristic of the effects of cocaine derivatives on the central nervous system. They occur when the quantity of solution exceeds the limit of safety, when the concentration of the drug is too high or when an inadvertent intravenous injection has been made. In this case, 45 cc. of a 2 per cent procaine hydrochloride solution might well be too high a concentration to use for infiltration anesthesia; if the solution injected was pontocaine hydrochloride in the same concentration, this far exceeds the limit of safety, as pontocaine hydrochloride is used in 1:1,000 to 1:500 dilutions for infiltration. The correspondent does not mention the concentration of the pontocaine hydrochloride solution.

It is usually considered unwise to operate on epileptic patients under local anesthesia, as they may develop convulsions on the operating table unless they are well premedicated with barbit-

urates or bromides. As the convulsions due to an overdose of the local anesthetic are due to cortical irritation, it is conceivable that the brain of an epileptic patient may be more sensitive to such intoxication than a normal brain; however, death here occurred almost certainly as a result of too much of the anesthetic or because of an intravenous injection. The latter may cause fatality in comparatively small doses.

XEROSTOMIA

To the Editor:—A woman aged 65 who is generally much debilitated has chronic gallbladder disease and is suffering greatly from xerostomia (dry mouth). The tongue is quite red and beefy in appearance, the lips are cracked, and voice production or articulation is difficult owing to a dryness felt in the esophagus and mouth. The blood picture is normal. I have been giving large doses of liver (Reticulogen Lilly) intramuscularly, 1 cc. weekly for four weeks, without any relief. Her general physical condition is decidedly under par. There is moderate arteriosclerosis with a mild hypertension. The nose and throat are otherwise negative. She has both upper and lower dental plates. Stomach analysis shows acidity. Therapy other than liver has included brewers' yeast tablets, diluted hydrochloric acid and moderate doses of digitalis for tachycardia. Any information you can give as to relief of dry mouth will be greatly appreciated.

M.D., Westmoreland, Kan.

ANSWER.—Xerostomia, or deficient salivary secretion, is an accompaniment of diabetes mellitus, diabetes insipidus, belladonna poisoning, severe fevers and nephritis. All dehydrated states are affected to a certain extent. While the condition is rather rare, all too often no assignable cause is demonstrable. In the absence of a specific cause, symptomatic treatment is resorted to with indifferent results. Glycerin mouth washes give some relief. Small doses of pilocarpine sometimes stimulate salivary secretion.

To discuss the possible causes of the fissured lips and the red tongue, apart from xerostomia, would carry the discussion from such local causes as eczema oris through a tremendous number of conditions up to a general nutritional deficiency such as pellagra or sprue. In the case cited, liver extract will not do much in the presence of a normal blood picture. Digitalis is usually ineffective in tachycardia that is not associated with heart failure. Anacidity is not uncommon at age 65 and hydrochloric acid may give symptomatic relief. Brewers' yeast may be useful.

A most careful search for a local or systemic cause should be pursued. If such search proves fruitless local treatment, unsatisfactory as it is, must be kept up.

GASTROINTESTINAL MELANOMAS

To the Editor:—Are melanomas ever primary in the gastrointestinal tract? How commonly are melanomas found in the gastrointestinal tract? How commonly are melanomas a cause of intestinal obstruction?

M.D., New York.

ANSWER.—Melanomas can be primary in the gastrointestinal tract. They occur almost exclusively in the rectum. According to Ewing (*Neoplastic Diseases*, ed. 3, Philadelphia, W. B. Saunders Company, 1928, p. 935) they constitute about 2 to 3 per cent of all melanomas. Of 266 malignant melanomas reviewed by Affleck (*Am. J. Cancer* 27:120 [May] 1936), only one such lesion was found in the mouth and in the rectum, respectively. Gerritzen (*Arch. f. klin. Chir.* 178:400 [Dec. 15] 1933) stated that seventy-two cases of primary melanoma of the rectum were reported up to 1934. Forty-eight of these actually were primary melanomas of the rectal mucous membrane, whereas the remaining twenty-four consisted of primary melanocarcinoma of the anus and melanocarcinoma. This author added an additional case of rectal melanocarcinoma to those already reported. Such tumors are found less frequently in the intestine and occasionally in the gallbladder, bile ducts, esophagus and mouth. Of course, in the presence of all melanomas situated in the last-mentioned sites, the question always arises as to whether they are primary or secondary manifestations. Melanomas are infrequently a cause of intestinal obstruction, partly because of their comparative rarity and partly because the majority of them are situated in the rectum. In a case of multiple primary melanomas of the small intestine reported by Menne and Beeman (*Am. J. Digest. Dis. & Nutrition* 3:786 [Dec.] 1936) there was no clinical evidence of obstruction prior to the operation. Maxwell (*M. J. Australia* 2:656 [Nov. 24] 1928) reported a case in which chronic intestinal obstruction and intussusception were the results of secondary melanomas of the small intestine.

An adequate bibliography may be compiled from the references to the literature in the textbook or in the articles of the authors cited.

QUERIES AND MINOR NOTES

190.

PUPILLARY ATONY WITHOUT SYPHILIS

To the Editor:—An examination of a veteran airline pilot reveals abnormal pupillary responses in that the pupils react sluggishly to light. Under strong light stimulation the pupils contract from 7 mm. to 4 mm. In the act of accommodation the pupils contract properly. Complete neurologic studies, including an examination of the blood and spinal fluid, yielded negative results. This pilot, at the end of frequent long flights and for a long period, has used a proprietary eye wash to relieve symptoms of mild eye irritation. The manufacturers of the eye preparation state: "This is a neutral and isotonic solution of boric acid and borax, containing 0.4 per cent antipyrine for its slightly anesthetic effect (see Sollmann, 'Manual of Pharmacology,' 5th ed., Saunders); small quantities of cherry laurel water and sodium salicylate are added as perfuming and preserving agents." Would a preparation such as this give false impressions as to pupillary responses?

Ralph Greene, M.D., Coral Gables, Fla.

ANSWER.—It seems unlikely that the use of the proprietary wash mentioned could have any influence on the normal pupillary action. However, it is barely possible that the pilot may be unduly susceptible to the influence of antipyrine, which is known to diminish muscular contractility (Bastedo, W. H.: *Materia Medica, Pharmacology, Therapeutics and Prescription Writing*, Philadelphia, The C. B. Saunders Company, 1937). It is more probable that this comes under the heading that Behr describes as "reflektorische Pupillenstarre bei nicht metakinetischen Erkrankungen" (pupillary atony without metasyphilitic disease). See Behr, C. J. P.: *Die Pupille in Hermann and Wilbrand, Saenger: Neurologie des Auges, Ergänzungs Band*, pages 181-197. It must be remembered also that the pupillary responsiveness to light is lost only gradually in syphilis.

AN INJECTION METHOD FOR VARICOSE VEINS

To the Editor:—In the three volume work entitled "Post-Graduate Surgery," edited by Rodney Maingot, there is a discussion of the injection treatment of varicose veins. A technic called "twin injections" is described in which quinine-urethane and a solution called lithocaine are injected simultaneously. Lithocaine is described as lithium salicylate 30 per cent, tutocain 1 per cent. Will you please tell me whether any one else has used these substances with the same degree of success as Maingot and, if they are used with the described consistently superior results, where they may be purchased?

M.D., Texas.

ANSWER.—The twin injection method of Maingot and Harvey has been used in several thousand cases by the authors, who reported no unpleasant sequelae and no pain. It seems unnecessarily complicated and requires two operators. No further reports in the literature are available. The solution could be made up by any chemical supply house; tutocain, a derivative of procaine hydrochloride, is not a harmless drug when injected intravenously.

HEMORRHOIDS IN INFANT

To the Editor:—Please advise me of the proper treatment of hemorrhoids in an infant aged 1 year. This child until recently had a persistent constipation and her stool was always large and hard. At the age of 9 months she had an anal fissure which lasted several weeks, after which a single hemorrhoid developed. At present she is having a daily bowel movement and takes liquid petrolatum daily. In spite of this the first portion of each stool is large, hard and inspissated. However, the mechanical action of the liquid petrolatum enables its passage without pain. Would you advise substitution of some hydrophilic substance for the oil?

M.D., Michigan.

ANSWER.—Hemorrhoids in an infant of 1 year practically never require surgical treatment. Constipation should be relieved and the stool kept soft and lubricated so as to avoid pain and irritation of the hemorrhoid on passage. Liquid petrolatum given daily usually suffices to accomplish this. If it does not there is no harm in using liquid petrolatum suspension. The diet should also be so arranged as to avoid constipation, i. e., with sufficient fruits, vegetables and laxative carbohydrates such as honey, lactose baby jams or corn syrups.

OSTEOMYELITIS IN MILKER

To the Editor:—Is there any danger in employing a farmhand who has a chronic osteomyelitis of the lower part of the leg to milk cows? Is there much likelihood that the organisms producing the osteomyelitis will produce intestinal or other symptoms if the milk is contaminated?

M.D., New York.

ANSWER.—It is probable that the danger of contamination of milk by a farmhand with chronic osteomyelitis of the lower part of the leg who is milking cows is fairly remote. Nevertheless, the possibility does exist that organisms from the infection might gain access to the milk. Furthermore, such organisms could produce intestinal or other symptoms if the milk was contaminated with them.

Practically, milk ordinances in general do not prohibit milking by a person with such an infection. If the milk so produced is not to be pasteurized, it would probably be better to prohibit milking by this man. He certainly should not be allowed to milk cows for the production of milk which is to be distributed raw.

PLASTIC SURGERY OF FACE

To the Editor:—I should like to buy a profilometer used or devised by Josephs, of Berlin, for measuring the profile of the nose in relation to the face. I have tried every store in New York without success. Would you please advise me where I can obtain this instrument and other plastic instruments for nose plastic work. Would you advise me whether there are any new books on plastic surgery.

M.D., Pennsylvania.

ANSWER.—A description of Dr. Joseph Safan's profilometer is found in his book "Rhinoplastic Surgery"; Dr. Safan was a student of Josephs. This has never been put on the market; one could have it made. Dr. C. L. Straith in Detroit uses one which could be duplicated. A celluloid triangle of 30 degrees held in such a way that one may view the profile is the simplest of all these. Dr. Ferris Smith, Grand Rapids, Mich.; Dr. Earl C. Padgett, Kansas City, Mo.; Dr. Joseph Safan, Dr. Arthur J. Barsky and Dr. J. Eastman Sheehan, New York, and Dr. Edmund B. Spaeth, Philadelphia, are among those who have recently written treatises on plastic surgery.

HERNIA IN INFANT

To the Editor:—At what age would you advise operation on an infant with an indirect inguinal hernia that goes into the scrotum when the baby cries? He has had this hernia since the age of 6 months and is now 1½ years old. A well fitted truss has not helped the situation, although he has been wearing one for the past six months. Also please give me your opinion on the injection, or sclerosing, method of treating a hernia in an infant of this age.

C. A. Eisner, M.D., Pittsburgh.

ANSWER.—Except in case of strangulation or incarceration it is a wise policy to postpone operation for hernia in an infant until he has reached the age of about 2 years, first because (1) the structures have by that time become well enough developed to make operation simple and easy and (2) before that period a baby ordinarily has not acquired habits of cleanliness and therefore the likelihood of infection of the wound has to be seriously considered. In the specific case referred to, operation had best be done even though the child has not reached the age of 2 years. The technic of procedure in an infant requires only the complete removal of the sac, and no repair of the inguinal canal is necessary. There is little, if any, likelihood of recurrence if this simple technic is carried out. This procedure has been tried much more often than the injection method of treatment.

NAUSEA FROM EPHEDRINE

To the Editor:—What is the best way of combating the complication of nausea induced by the use of compounds of ephedrine in the treatment of bronchial asthma?

Howard B. Brown, M.D., Springfield, Mass.

ANSWER.—The nausea which occasionally accompanies the use of ephedrine compounds in full therapeutic doses is due to its local irritant action on the gastric mucosa. This occurs in only a relatively small number of persons. It has been stated that asthmatic patients seem to be more susceptible to the local irritant action of ephedrine compounds. The sulfate may be less irritant than the hydrochloride and should be used when there is any question of local irritability. An enteric coating may be tried to obviate the gastric irritation. In some cases the use of small amounts of barbitol or its derivatives or, still better, of brometone has given relief. The brometone may be given with the ephedrine. And finally the use of a solution of sodium bromide in rather small doses has been of benefit in cases such as described.

ANTIEMETIC POTENCY OF LIVER

To the Editor:—Referring to the inquiry concerning the comparative antiemetic potency of calf's liver and lamb's liver (*The Journal*, August 5, p. 530) I wish to advise that I have prepared and tested liver extract prepared separately from beef liver, pork liver, lamb liver and salmon liver. I was unable to detect any great difference in the antiemetic potency of the extracts prepared from the three mammals. I had considerable difficulty in extracting the fish liver and can only state that the extract as finally obtained was much less active, in the neighborhood of 50 per cent.

Guy W. Clark, Ph.D., Pearl River, N. Y.

Book Notices

Training for Championship Athletics. By C. Ward Crampton, M.D. Cloth. Price, \$2.50. Pp. 303, with 7 illustrations. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1939.

As the title suggests, Dr. Crampton's book is designed primarily to attract and interest boys and young men. It should do both. The author is well qualified by long experience as an athlete, teacher of athletes and physician to athletes to write of the making of athletes. He does it brightly and effectively, with real analytic ability. So well is the job done that it should make helpful reading for others than prospective athletes, particularly coaches and physical education teachers. In content the volume presents general material on training for various athletic activities, growth, development and diet, much of it made spicy and interesting by being directly connected with prominent athletes such as Bob Feller and Glenn Cunningham. The styles, habits and training methods of a number of such athletes are discussed in a way to stimulate and intrigue the average boy. The latter part of the book is devoted to more specific and detailed matters of diet and technique for various sports. Included are sprinting, mile running, pitching, batting, basketball and fundamentals of football. There are many helpful illustrations from photographs of great athletes and the type is large enough to be easily readable.

Medicolegal Phases of Occupational Diseases: An Outline of Theory and Practice. By C. O. Sappington, A.B., M.D., Dr.P.H. Cloth. Price, \$2.75. Pp. 405, with 7 illustrations. Chicago: Industrial Health Book Company, 1939.

Extension of workmen's compensation to include indemnification for disability arising from occupational disease is of comparatively recent origin. Nevertheless there are sound indications already that this development has come to be a major preoccupation in the field of medical jurisprudence. Even a satisfactory definition of what constitutes an occupational disease is extraordinarily hard to reach. When one adds to that fundamental difficulty the associated problems of etiology, disability rating and adjudication, the whole picture becomes one of fascinating complexity. In the construction of a work on occupational disease compensation, therefore, there is at once the necessity of picking out and emphasizing those principles which have received the imprint of judicial and authoritative interpretation. In these respects the author has succeeded admirably. The subject matter, all closely constructed after the handbook style, is treated under four major headings: industry, insurance, medicine and law. The first section deals largely with lists and classifications of industrial hazards. There are also chapters on detection and control from the engineering standpoint which will be of interest to physicians not entirely aware of the considerable advances being made along these lines. The section on insurance testifies for the most part that successful principles for underwriting this type of risk are by no means settled. Past experience in compensating for industrial injuries, valuable as it has been, will provide only a partial solution to the perplexing problems of disability arising out of occupational disease. The economic and social impacts of this movement, especially the medical contribution and particularly past relationships which have existed between medicine and insurance in the casualty fields, are evidently outside the scope of this book. The chapters devoted to medical considerations concern themselves with classifications of exposures according to cause and part affected. Throughout this discussion the need for thorough study of etiology is constantly underlined. Disability estimation largely follows Kessler's previous work. There are only brief references to medical treatment, which because of its unsatisfactory character should occupy a secondary position to preventive principles. The legal section receives the most extensive consideration. There are tables on incidence collected from the few states that publish data on closed occupational disease claims. The controversial details of blanket versus schedule coverage are presented as well as the merits and disadvantages of court procedure, industrial commission

practice and the use of medical advisory boards. An appendix contains digests of workmen's compensation laws affecting occupational diseases and also abstracts of court decisions which will be interesting to physicians who have had contact with legal procedure in sufficient degree to allow for proper appraisal.

Urine: Examination and Clinical Interpretation. By C. E. Dukes, M.Sc., M.D., D.P.H., Pathologist to St. Peter's Hospital for Stone and Other Diseases of the Urinary Organs, London. Cloth. Price, \$8. Pp. 403, with 110 illustrations. New York, Toronto & London: Oxford University Press, 1939.

As stated in the foreword, the author has attempted to collect methods of laboratory procedure for investigations on the urine useful in clinical practice. He has devoted much space to the clinical interpretation of these laboratory results. This experience has been gained as a result of ten years' service as clinical pathologist to a hospital majoring in the care of patients with urinary tract diseases. The volume is well printed on good paper, adequately indexed and contains excellent photographs, some of which are presented as colored plates. Many references to original articles are given and the volume should serve as an excellent guide to laboratory workers. Errors in proof reading are nil, although on page 21 hippuric acid is referred to as a conjugated product of benzoic acid and glycerin. However, this compound is described correctly later. The book is stronger in the section devoted to microscopic and bacteriologic technics than to the chemical procedures.

Many essential chemical procedures, at least so regarded in the United States, have been omitted. Some of these omissions might be cited. Better tests for the recognition of bile salts utilizing the Pettenkofer reaction are available than those given. In the determination of the p_n value of urine, no mention is made of the quinhydrone or glass electrode methods, although the quinhydrone method is of quite common use since the apparatus is economical, accurate in the range of urine, and avoids the pitfalls of the colorimetric procedures in a solution such as urine, which may be at times highly colored. It would seem that qualitative tests for the presence of urea in urine are superfluous and should not be emphasized. The hypobromite method has been almost entirely replaced in this country by the urease procedure. No mention is made of boric acid as an absorbent for ammonia in the aeration procedure for determining urea, although this absorbent is commonly used and obviates the necessity of one standard solution. Only the Benedict uric acid method is given and no reference is made to the direct procedure. Similarly, the excellent method of Sullivan for recognition of cystine is omitted. This method serves admirably for identifying cystinuria as well as the recognition of cystine calculi.

The chapter devoted to hormone assay is a welcome addition to a modern reference work, but here again there is a lack of procedures which are now recognized as useful clinically. No test is described for the determination of the corpus luteum hormone as it is excreted in the urine as pregnandiol glucuronate. The Oesting chemical method for determining androgen is not given nor is there any mention of the lactogenic hormone.

To workers in other countries it would seem that the metric system of measurement should be followed completely. Body weights would not then be referred to as so many stone, such as is given in the section devoted to vitamin C. Chemical tests for vitamins B₁ and B₂ are not presented even though this determination is at present on a quite quantitative basis. The Koppanyi test for barbiturates in the section on recognition of poisons is not included, although it would seem that this method offers the best quantitative technic for the determination of this group of substances.

There is an extended chapter on urinary calculi with excellent illustrations and undue detail for one who is interested in the laboratory angle solely. Usually the pathologist is interested mainly in the type of calculus that is present in order to give the clinician information on which to base therapeutic procedure. The determination of the type of calculus is a simple accomplishment and can be done following the procedure given by the author. However, acetic acid is usually

the acid of choice in the differential acidification for the recognition of calcium phosphate and calcium oxalate.

Essentially this volume offers much of value to the laboratory technician and to the general practitioner by presenting in a simple manner laboratory urinary technic in a concise form.

Die Tuberkulose als Allgemein-Krankheit. Von Dr. G. Liebermeister, Leiter der Inneren Abteilung des Städtischen Krankenhauses Düren. Nr. 72, Tuberkulose-Bibliothek, Beihette zur Zeitschrift für Tuberkulose. Herausgegeben von Dr. Franz Redeker, Oberregierungs- u. Obermedizinalrat, Berlin, und Dr. Karl Diehl, dirigierender Arzt, Sommerfeld. Paper. Price, 12 marks. Pp. 108, with 23 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

This small volume will be of interest to the specialist in tuberculosis but of less concern to the general practitioner and specialist in other diseases, in spite of the fact emphasized by the author, to which exception cannot be taken, that the general manifestations of tuberculosis are such that internists, pediatricians, surgeons and physicians in the specialties should be familiar with them. Liebermeister's book represents a mixture of clear summarizing of accepted facts and an attempt to explain them in a complicated way that will seem unnecessarily confusing to all not versed in the varying terminology built around the phenomenon of allergy. Clinicians with long experience in tuberculosis, in turn, are apt to take frequent exception to the rather glib explanations of variation in the course of tuberculosis in terms of energy, dysergy and nomerger and to feel that commonly the course does not conform with the diagrams in the text intended to illustrate stages of the disease. Specialists in tuberculosis, however, will find the author's conceptions stimulating in directing attention to the relations of allergy and illness.

Hygiene. By J. R. Currie, M.A., M.D., D.P.H., Henry Meehan Professor of Public Health, University of Glasgow, Glasgow. Cloth. Price, \$5. Pp. 324, with 34 illustrations. Baltimore: William Wood & Company, 1938.

This textbook on hygiene is described by the author as intended for the use of students of medicine, priority being given to the social aspect of hygiene. Although Currie states that he does not elaborate the administrative and legal points of hygiene, one third of the book describes rather fully the provisions in Great Britain for medical and public health care, including maternal and child welfare, school hygiene, mental hygiene and industrial hygiene. One chapter is devoted to a discussion of social insurance as it is employed in Great Britain. This discussion is largely an enumeration of the laws which have been passed and the benefits available to individual citizens without any opinions being given with regard to the effectiveness of such legislation. The remainder of the volume takes up various aspects of personal and environmental hygiene, such as food, ventilation, lighting, water supply and waste disposal, and gives a rather detailed treatment of the individual infectious diseases. This book should serve the purpose for which it is written, that is, as a textbook on hygiene for medical students in Great Britain. Because much of the material is concerned with specific legislation and practices in that country, its chief value in the United States will be as a reference book for those wishing to get information on practices in Great Britain.

Les troubles de la thermorégulation (coup de chaleur). Par L. Déröbert. Paper. Price, 60 francs. Pp. 218, with 13 illustrations. Paris: Masson & Cie, 1939.

This work is an experimental study the purpose of which is to determine the pathology of the clinical group of symptoms known as heat stroke. Two thirds of the monograph consists of a survey of the literature that the author considers has a bearing on the subject. Although there are twenty-five pages of bibliography, the American work on the subject is incomplete and most of the authors mentioned in the text cannot be found in it. The author exposed dogs, rabbits and guinea pigs to high humidity and temperatures ranging from 40 to 45 C. (104 to 113 F.), studied the clinical effects and examined them post mortem. The first group of animals died in from thirty-five to seventy-five minutes. The second group also exposed to high humidity and to lower temperatures, 32 to 35 C. (89.6 to 95 F.), survived. The physical and clinical changes were noted and they were later examined pathologically. The final group consisted of a case of heat stroke and

one of severe burns in human beings. Descriptions with illustrations of the morphologic changes in the blood cells were given and some measurements of the chemical constituents of the blood recorded. The author concludes that "elevated temperature on one part of the body or on the whole body is capable of causing benign symptoms (syncope and collapse) or serious symptoms (properly known as heat stroke) the cause of which is disintegration of the albumins. . . . Although this disintegration is important, the marked increase of 'albumoses' causes lesions as important as those found in anaphylactic shock. These 'albumoses' can cause the same lesions in an organism previously sensitized even though it is not specific, or in an organism in which the antitoxic barriers are deficient. . . . This produces a disintegration of the first importance in which the polypeptides cause lesions of the vegetative centers, which in their turn are responsible for changes in the organ as a whole." The evidence cited for these conclusions is inconclusive. The relation of the metabolism of water and the electrolytes to shock might have been discussed with advantage.

M One Thousand Autobiographical Sonnets. By Merrill Moore. Cloth. Price, \$5. Pp. 1,000. New York: Harcourt, Brace & Company, 1938.

This book is cleverly titled with the metric symbol for a thousand, which happens also to be the author's initials. It contains 1,000 sonnets of 50,000 which he has written, though he pledges himself that most of the rest will not be published. These sonnets are in many different forms. A considerable number present the traditional octet and sextet of the established form for this poetic medium. Others are differently divided, one for example consisting of couplet, triolet couplet and triolet quatrain, with the second line of the latter broken in two. There are others in two stanzas of seven lines, some in three-five-three and three, and still others in five-two-two and one. The rhythm is as causal and irregular as the stanza divisions. Lines are frequently broken in the middle. Rhymes appear or are ignored, at the author's pleasure. The sonnets are said to be autobiographic, but the reader would have difficulty recognizing this fact if his attention were not called to it by the introductory statement. The work does show strongly the influence of his medical training and his interest in psychiatry, since many of his sonnets deal with medical matters, as, for example, "There Was A Man":

. . . He was born in Wurttemberg,
Came to America at twenty, never married,
Never missed operas, and always tarried
Before antique shop windows and before
Shops where meerschaum objects and where amber
Were displayed, and never spoke English well,
And got along very quietly till he fell
And broke his hip.
Pneumonia ended his life
In Bellevue neatly stretched between two sheets
By crevasses and canyons that were streets.

Other sonnets deal with the psychology of deafness, "Ambulance Call," and a satire on the gyrations of the bald entitled "Too Late for Herpicide." A whole division is devoted to dreams and symbols and in this is included a tricky "Sonnet in Code" and one composed almost exclusively of Pullman names and other words. There is such endless variety of form and topic in this book that should make it provocative and stimulating reading for one who can pick it up and read it by snatches. In fact, the reviewer is not inclined to hold the author to his promise of nonpublication of the rest of his work, or at least a portion of it.

Short Stature and Height Increase. By C. J. Gerlling. Cloth. Price, \$3. Pp. 159, with illustrations. New York: Harvest House, 1939.

The title is intriguing but may lead the man of short stature, to whom this book is addressed, to expect far more than the author can deliver. The author does not promise in the various chapters to increase the height of the individual but points out the various factors that may produce an illusion of increased height. The book is interestingly and simply written and presents the various factors responsible for growth. Inheritance, the mechanism of growth and all the factors as glands, food, sleep, age and disease are discussed in their relationship to growth. The author then tells of the folly of using highly advertised self-prescribed drugs and devices to bring about an

increase in height. There is a brief but excellent discussion of the little faith that should be placed on weight tables based on age and height. The main thesis of the book is that posture is the best and surest aid for those of short stature. It can bring about an actual increase in height only so far as the person has allowed himself to assume a slouch. The benefits of exercise to increase the tone of the muscles responsible for good posture may result in better health and a better appearance and with it a better outlook on life. The chapter on stature aids is of interest in that it discusses shoes and clothing and the part they play in producing illusions of greater height. It is a book that the practicing physician may want to recommend to his patients whose short statures are keeping them from a normal, cheerful outlook on life.

Life and Letters of Dr. William Beaumont. By Jesse S. Myer, A.B., M.D. With an introduction by Sir William Osler, Bt., M.D., F.R.S. Second edition. Cloth. Price, \$5. Pp. 327, with illustrations. St. Louis: C. V. Mosby Company, 1939.

Here is a new printing of the famous book by Myer first published in 1912. It still bears the introduction which Dr. William Osler wrote at that time. The name of Beaumont is almost supreme among workers in the field of physiology in this country as our greatest pioneer. At the meeting of the International Congress of Physiologists in Boston in 1929, William Beaumont was figuratively canonized as the Patron Saint of American Physiology. In a new introduction by Dr. A. C. Ivy there is an analysis of present day points of view in relationship to Beaumont's experiments. The present volume contains a reproduction of the fine painting made by Dean Cornwell in 1938 and is otherwise similar to the edition published in 1912. This book is a "must" item for every American physician interested in medical history.

Otolaryngology in General Practice. By Lyman G. Richards, M.D., Associate Professor of Otolaryngology, Tufts Medical School, Boston. With a foreword by D. Harold Walker, M.D., Consultant in Otolaryngology, Massachusetts Eye and Ear Infirmary, Boston, Massachusetts. Cloth. Price, \$6. Pp. 332, with 72 illustrations. New York: Macmillan Company, 1939.

This textbook on otolaryngology for use by the general practitioner accomplishes its purpose in an admirable way. The author discusses the most common diseases and complaints which the general practitioner is called on to take care of in everyday practice. The impression one gets on reading the book is that here are the opinions of a person of experience, unmarked by strong personal bias and characterized by a great deal of good common sense. The author has not described in great detail operations which the general practitioner has no right to do and which he is not called on to do. The one operation on which time is spent is that of tonsillectomy and adenoidectomy, and this is eminently proper because, regardless of contrary opinion, most of the tonsillectomies in this country are being done by nonspecialists. The general practitioner interested in diseases of the ear, nose and throat can gain much by a careful reading of the text.

Headache and Head Pains: A Ready Reference Manual for Physicians. By Walton Forest Dutton, M.D., Director, Medical Research Laboratories, Amarillo, Texas. Cloth. Price, \$4.50. Pp. 301, with 6 illustrations. Philadelphia: F. A. Davis Company, 1939.

Headache is a symptom which may occur with almost any disease affecting the human body. To attempt to give a differential diagnosis of headache with treatment would involve a complete knowledge of all phases of medicine. One volume, as one can readily see, would be quite inadequate. The introduction deals with the neurophysiology, etiology, analysis of causal factors and discussion, including history and method, for relief of pain. This part in itself, although superficial, is fairly well written. Opium is mentioned as the most important analgesic, a statement with which the reviewer would not agree. The rest of the book deals with diseases causing headache and their treatment. This is arranged alphabetically instead of in order of their importance. Such a common condition as sinus disease is given two pages and so is the rare condition actinomycosis. Brain tumor is said to be a common disease, which is an erroneous statement; opium derivatives are prescribed, which are actually contraindicated in most

cranioerebral diseases and injuries. Functional disturbances are erroneously handled only with drugs. Although the book has a few good prescriptions, the reviewer can see no value for even the layman and certainly not for the practitioner or specialist.

Index-Catalogue of the Library of the Surgeon General's Office, United States Army (Army Medical Library). Authors and Subjects. Fourth Series. Vol. IV: Daac-Dzionara. [Including] Specimen Pages from a Bio-Bibliography of XVI. Century Medical Authors [and a] First Addition to the Reference List of Congresses. Cloth. Price, \$2. Pp. 756. Washington, D. C.: Supt. of Doc., Government Printing Office, 1939.

The fourth volume of the fourth series of the Index Catalogue of the Surgeon-General's Office covers the letter D. The Surgeon-General's Library now contains approximately 409,223 volumes, 377 pamphlets and almost 200,000 theses. About 18,000 new items are added to the library each year. Recently the subscriptions of the library have been extended by some 200 new medical journals, of which approximately 50 per cent are South American and 15 per cent from soviet Russia. This work has long been known as a competent index to the material that it covers. In the current issue the headings dementia, dentistry, digestive tract, disability and drugs as well as dermatitis, diabetes, diarrhea and diet indicate the importance of the letter D in any medical classification.

Pratsi y materiali pershogo Kharkivskogo Derzhavnogo Medichnogo Institutu. Vidpovidalnyi redaktor: A. Gasparyan. Vypusk X: Organogumoralna regulatsiya i aktivni metodi likuvannya. Chastina 1: Giperatsidni gastriti. [Works and Materials of First State Medical Institute of Kharkov. Volume X: Organohumoral Regulation and Active Methods of Treatment. Part 1: Hyperacid Gastritis.] Cloth. Price, 5 krb. Pp. 128, with illustrations. Kiev: Derzhavne medichno vidavnistvo, 1938.

This small volume of papers from the department of internal medicine headed by Prof. A. P. Korkhov of Kiev deals with acid gastritis. Korkhov develops the thesis that a number of diseases of the liver, stomach, duodenum and biliary tracts have for their basis a shift to acidosis in the blood and tissues. He therefore advocates in the treatment of acid gastritis and gastric ulceration, besides the rest and the diet, alkalization of the organism by administration of sodium bicarbonate and magnesium carbonate in the proportion of 4:1 based on consideration of the determined physicochemical indexes of the urine, the blood and the gastric juice. The text is in Ukrainian, with a summary in Russian and in French.

A Survey of Child Psychiatry Contributed by Contemporary British Authorities. Edited on behalf of the Child Guidance Council by R. G. Gordon, M.D., D.Sc., F.R.C.P., Medical Director Child Guidance Council. Cloth. Price, \$3.50. Pp. 278. New York & London: Oxford University Press, 1939.

Here a number of prominent British writers discuss child psychiatry under the special headings of physical illness, mental illness, sociologic aspects and special syndromes. The latter concern chiefly enuresis, stammering, sleep disorders, ties and sexual difficulties. A book of this type indicates how far we have advanced in our study of the child since the leaders of medical and social science began to give these problems special attention. It is interesting to know that the Commonwealth Fund of America aided in setting up a demonstration clinic in London and was really responsible for introducing the whole field of child guidance into Great Britain. The competent articles here presented are an indication of the great advancement that has been made.

Evaluation of the Industrial Hygiene Problems of Illinois. Prepared by Division of Industrial Hygiene. State of Illinois, Department of Public Health, A. C. Baxter, M.D., Director. Paper. Pp. 258. Chicago, Illinois, 1939.

A series of industrial hygiene surveys have been conducted by divisions of industrial hygiene in state health departments operating under plans and instructions originally devised by the United States Public Health Service. As a result the publications of the individual bureaus of industrial hygiene take on aspects of uniformity which, in the event of subsequent compilations on a countrywide basis, will provide data of inestimable value. Even if such were not the case, a review of the industrial hygiene problem in Illinois because of the variety of its manufacturing processes takes on aspects of

importance which transcend mere local interest. In this instance the great number of tables which list the major exposures of all the principal occupations occurring in the state and the percentage of workers exposed to specified materials in those occupations make it in many respects the most useful of the state reports yet published. The compilers of this report consider it merely a statistical presentation. It is likely that a future publication will present an industrial hygiene program for the state based on this preliminary fact finding investigation.

The International Medical Annual: A Year Book of Treatment and Practitioner's Index. Edited by H. Letheby Tidy, M.A., M.D., F.R.C.P., and A. Rendle Short, M.D., B.S., B.Sc. Fifty-Seventh Year, 1939. Cloth. Price, \$6. Pp. 602, with 196 illustrations. Baltimore: William Wood & Company, 1939.

This volume is now in its fifty-seventh year. A considerable number of British physicians cooperate in producing the book, which resembles the American Year Book series except for the fact that here everything is in one volume. There is an extensive index and the book is beautifully illustrated. Each of the articles concerned is supplemented with a suitable bibliography. Practically all the articles concern papers published during 1937 and 1938.

Gastrointestinal Dysfunction. By Barton Arthur Rhinehart, A.B., M.D., Associate Professor of Roentgenology, University of Arkansas School of Medicine, Little Rock. Cloth. Price, \$6. Pp. 311, with 48 plates. Little Rock, Arkansas: Central Printing Company, 1939.

This is a comprehensive title, but the student or physician who hopes to discover in this volume a comprehensive treatise dealing in detail with the many and varied types of functional disorders of the digestive tract will meet with disappointment. It is not a textbook. The author states on the flyleaf: "This book is dedicated to the proposition that nutritional deficiencies cause the majority of the gastrointestinal disorders of civilization" and he attempts to promulgate this highly debatable theory by assembling a great and extremely heterogeneous mass of material quoted from the writings of clinicians, investigators in the field of metabolism and others. The author is himself a roentgenologist. It is unfortunate that the equipment he was able to bring to his task did not include a requisite fundamental knowledge of disorders of the gastrointestinal tract.

Richtlinien praktischer Orthopädie. Von Dr. Albert Lorenz. Paper. Price, 15 marks. Pp. 464, with 123 illustrations. Vienna: Franz Deuticke, 1939.

The author, who apologizes for the similarity of his name to that of the father of German orthopedics, Adolf Lorenz, proposes his book for the use of specialists. He attempts to present only material which he considers of proved value; etiology and unusual symptomatology are handled more briefly than therapy and surgery; scientific experiments are given secondary consideration to practical experience and the general trend is conservative. The subject matter covers the complete category of practical orthopedic problems and their treatment. The fracture problem is confined to a discussion of fractures of the neck of the femur. This volume serves as a good compilation of current ideas in orthopedics. The author quotes freely from the American literature throughout the book, a large portion of which was written in New York. Although the material presents little originality, the discussions are adequate.

Arthritis in Women: A Clinical Survey with Notes and Statistics from Representatives of Committees on Rheumatism in Various Countries, and a Statement on the "Campaign Against Rheumatism, Retrospect and Outlook" (1935). Also a Suggestion for Setting up Rest Houses for Rheumatoid Arthritis. By R. Fortescue Fox, M.D., F.R.C.P., F.R.Met. Soc., President of the International League against Rheumatism. Founded on a Lecture Delivered at the Institute of Hygiene, London, April, 1936. Paper. Price, 2s. 6d. Pp. 35. London: H. K. Lewis & Co., Ltd., 1936.

The clinical course of arthritis in women is described. The material presented is accurate and well developed, but one would expect a great deal more from the title of the pamphlet. The pathology of arthritis is barely mentioned. The ideas of rest homes and spa treatments are not new but deserve emphasis at this time.

Trudy Stalingradskogo Gosudarstvennogo Meditsinskogo Instituta. Tom I. Pod redaktsey A. I. Bernshteyna, S. N. Kasatkina i A. Ya. Pytel'skiy. [Works of Stalingrad Medical Institute. Volume I.] Cloth. Pp. 137, with illustrations. Stalingrad: Oblastnoe knigoizdatel'stvo, 1939.

The volume consists of a monograph on the development of sesamoid bones in man and a medley of unrelated subjects. It presents little of interest to physicians and does not lend itself to review.

The Story of a Baby. By Marie Hall Ets. Cloth. Price, \$2.50. Pp. 63, with illustrations by the author. New York: Viking Press, 1939.

At the Century of Progress Exposition in Chicago in 1933 and 1934 one of the items of greatest interest was the exhibit of human embryos. In this beautiful book the author has redrawn the embryo and supplies a text printed in large type. She describes succinctly and beautifully the development of the baby. Many a parent will find a book of this type exceedingly useful in telling the story of childbirth to children of various ages.

English-German and German-English Medical Dictionary. Part I: English-German. Englisch-Deutsches medizinisches Wörterbuch. By Adalbert Springer. Fifth edition. Cloth. Price, 6 marks. Pp. 201. Vienna: Franz Deuticke, 1939.

This little medical dictionary is useful as far as it goes but omits a considerable number of words which might frequently need to be consulted, such as calibration, arrhythmia, fibrosis, ambulatory and sedation. The book is indicative of the relative ineffectiveness of any kind of dictionary which is not truly inclusive.

The Genuine Works of Hippocrates. Translated from the Greek by Francis Adams, LL.D. With an introduction by Emerson Crosby Kelly, M.D. Cloth. Price, \$3. Pp. 384. Baltimore: Williams & Wilkins Company, 1939.

This translation of Hippocrates has been reprinted many, many times, and there continues to be a demand for it. The present edition is put out in good paper, with a suitable binding, and has an index.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Silicosis: Death of Employee Attributed to Failure of Employer to Provide Safe Place of Work.—The plaintiff sued the defendant corporation to recover damages for the death of her husband. She alleged that he died from silicosis, contracted as a result of the failure of the defendant to provide him with a reasonably safe place in which to work. The trial court gave judgment for the plaintiff and the defendant appealed to the Supreme Court of Pennsylvania.

The plaintiff's husband was employed from 1924 to 1935 as an operator of a segment grinder, used for polishing ceramic or pottery products manufactured by the defendant. In October 1935 he was admitted to a state sanatorium for the treatment of tuberculosis and remained there until he died, Feb. 9, 1936. The plaintiff contended that the defendant failed to provide the grinder with an adequate hood and a sufficient device, such as a suction fan and pipe, for carrying away the dust. She charged that excessive quantities of dust containing free silica were released into the atmosphere about the machine and that as a result of inhaling this silica-laden air over a period of years her husband contracted silicosis, which brought about the tuberculous condition causing his death. The defendant was negligent, she further contended, because it failed to supply the employee with a dust mask of the character customarily worn by operators of such grinding machines. According to the plaintiff, the dust hazard arose because the defendant violated the provisions of a Pennsylvania act passed in 1915 requiring that "The owner or person in charge of an establishment where machinery is used shall provide . . . exhaust fans of sufficient power, or other sufficient devices . . . for the purpose of carrying off poisonous fumes and gases, and

dust from emery-wheels, grind-stones and other machinery creating dust." The plaintiff's evidence went to show that, although an exhaust fan was installed at the machine which her husband operated, it was not of sufficient power to carry off the dust produced; that the mechanism of the fan was not kept in working condition, and that the defendant failed to warn the employee of the dangers to which he was subjected in breathing the dust.

The defendant denied that the plaintiff's husband died of silicosis, claiming that the cause of his death was pulmonary tuberculosis contracted from causes having no relation to the conditions of his employment. It claimed that there was not a sufficient amount of free silica in the atmosphere about the grinder to cause silicosis. It further contended that it complied with the provisions of the Act of 1905 by attaching to the machine a dust-removal appliance of the best type available and in general use throughout the industry, that it provided the employee with a mask for his use but that he neglected to use it and, finally, that the employee was guilty of contributory negligence.

The disease to which the plaintiff attributed her husband's death, said the Supreme Court, was occupational and therefore was not compensable at the time under the workmen's compensation act of Pennsylvania. The real question before the court, therefore, was whether the defendant furnished the deceased a reasonably safe place to work as measured by the requirements of the Act of 1905. The provisions of that act are mandatory, the court pointed out, and proof that the employer has failed to comply with the duties imposed thereby and that an employee, without negligence on his part, has been injured as a result of such failure constitutes negligence, rendering the employer liable for the harm so caused. While the plaintiff admitted that there was a cover over the wheel and that a suction fan was installed by the defendant, it was denied that they were sufficient to eliminate the accumulation of dust in the atmosphere. It was not disputed by the defendant that the fan and cover were inadequate to carry away the dust about the grinding machine. The defendant urged, however, that it was not an insurer of the employee working at a dangerous piece of machinery and that it performed its full duty under the statute when the preventive devices which it adopted were of the kind generally approved and in use in like plants throughout the country. But, said the court, merely because the particular device employed was similar to that "generally approved and customarily used" in the industry of itself would not exonerate the defendant of the charge of negligence. While the custom or practice prevailing in a particular business in the use of methods, machinery and appliances is a most important factor in determining the question of negligence, ultimately it is for the jury to ascertain whether under all the circumstances the defendant was negligent. And certainly ordinary usage in disregard of a statutory duty cannot relieve the defendant of liability for a failure to respond to the legislative mandate. Whether or not the defendant in the present case was negligent presented a question for the jury to decide, and its finding for the plaintiff, the court said, compels the conclusion that the device used by the defendant was insufficient. An ineffective and feeble device is no more a fulfilment of the legislative demand than no device at all. The shadow of compliance will not be accepted for the substance of the statutory requirement.

There was some conflict in the evidence as to whether the death of the employee was caused by silicosis or by pulmonary tuberculosis. He inhaled a vast quantity of the dust particles in consequence of his constant exposure to them. The testimony was at variance on the question whether the atmosphere contained free silica in sufficient quantities to cause silicosis. The plaintiff produced evidence to the effect that silicosis could result from the constant inhalation of dust particles containing even a minute quantity of free silica. Experts testified that an autopsy disclosed the presence of "gritty" substance, scar tissue and "nodules" in the decedent's lungs, indicating that he suffered from silicosis. Other "nodules" were found pointing to a tuberculous as well as a combined tuberculous and silicotic condition. In the light of such testimony, the court said, it cannot be said that the jury's determination of this question is not supported by the record.

Ordinarily available in master-servant cases, the defense of assumption of risk is not permissible where the employee is injured through the failure of the employer to comply with a legislative requirement such as contained in the Act of Pennsylvania of 1905. Although the employee in the present case may have been aware of the presence of the dust in the factory, it is, the court said, extremely doubtful that he was conscious of the real risk involved, the danger of the contraction of silicosis. Such a degree of scientific knowledge is not to be attributed to an ordinary factory employee. The defendant contended that the employee was negligent in failing to use the dust mask with which he was provided. The plaintiff's witnesses testified, however, that no workable masks were supplied, since those furnished were unfit for use. Here again the question of contributory negligence was one for the jury to decide, and the Supreme Court could find no reason to disturb the finding of the jury with respect to this matter.

After a thorough review of the record, the Supreme Court of Pennsylvania affirmed the judgment of the trial court for the plaintiff.—*Price v. New Castle Refractories Co. (Pa.)*, 3 A. (2d) 418.

Optometry: Cooperative Arrangement Between Optical Company and Physicians as Practice of Optometry.

—In this suit, the State of Iowa on relation of the Commissioner of Health sought to enjoin the defendants from practicing optometry without a license. The trial court issued the injunction and the defendants appealed to the Supreme Court of Iowa.

The state undertook to sustain the injunction on the ground that the arrangement entered into between the defendants and the physicians constituted an employment agreement and that the employment of one legally authorized to practice optometry in the state of Iowa by an unlicensed person or corporation is prohibited by statute. The business of the defendants consisted of selling eyeglasses or spectacles by filling prescriptions prescribed by authorized persons and selling optical merchandise. They were opticians. Their practice was to rent an office consisting of one or more rooms adjacent to the rooms in which they carried on their business and to arrange with a licensed physician to occupy such rooms and practice optometry. The defendants paid the rent, light, heat and telephone bills and furnished all the equipment used by the physician in examining and testing eyes. The examination fees charged by the physician, which ranged from \$1 to \$2, belonged to him. None of the earnings of the physician belonged to or was paid to the defendants. The defendants, however, guaranteed the physician that his earnings would be \$40 a week. If the earnings were under that sum they would pay him the difference. While there was some testimony to the effect that the physician was not obligated to send patients to whom prescriptions had been given to the defendants, the court was convinced that the real arrangement was that the defendants would send all persons who came to their establishment without a prescription, and who desired glasses, to the physician and that the physician was to direct his patient to the defendants for the purpose of having his prescription filled.

In the opinion of the court, the state failed to establish its contention that the relationship of employer and employee existed between the defendants and the physicians. No witness testified that the defendants under the arrangement had the right to control or influence a physician in making the examination, and the test of the employer-employee relation, the court continued, is the right of the employer to exercise control of the details and method of performing the work. After reviewing the facts in this case, the court was convinced that the defendants did not have that right under the arrangement it had with physicians. The physicians, all of whom had practiced prior to the arrangement, were not performing the business of the defendants but were carrying on their own business of optometry under a reciprocal arrangement with the defendants for the mutual financial benefit of both parties. When a patient came to consult one of these physicians there was the personal relationship of patient and physician between them. The physicians, in making the refraction, represented the patient and not the defendants. The record showed that the business of the defendants was materially increased by the

arrangement. The court was satisfied after a careful reading of the record that the defendants did not coerce or influence the physicians relative to prescriptions. The profession of the physicians and the business of the defendants were separate and each operated independently of the other.

The defendants urged that the employment of one legally authorized to practice optometry in Iowa is not forbidden by statute, and even if the arrangement did constitute an employment contract it did not constitute the practice of optometry by the defendants in violation of the laws of the state. With this contention, however, the Supreme Court disagreed and in doing so reaffirmed the interpretation placed on Iowa laws and the principles announced in two previous cases, *State v. Kindy Optical Company*, 216 Iowa 1157, 248 N. W. 332, and *State v. Bailey Dental Company*, 211 Iowa 781, 234 N. W. 260.

The decree of the trial court enjoining the defendants from practicing optometry was therefore reversed and the case remanded.—*State ex rel. Bierring, Commissioner of Public Health, v. Ritholz et al. (Iowa)*, 283 N. W. 268.

Workmen's Compensation Acts: Compensability of Hernia.—The employee filed a claim for compensation under the workmen's compensation act of South Carolina, alleging that he had suffered a compensable hernia during the course of his employment with the defendant company. The industrial commission disallowed the claim, which action was affirmed by the common pleas circuit court of Spartanburg County. The employee then appealed to the Supreme Court of South Carolina.

The workmen's compensation act of South Carolina provides that in all claims for hernia alleged to have resulted from accidental injury sustained in the course of employment it must be definitely proved that there was an injury resulting in hernia; that the hernia appeared suddenly; that the hernia or rupture immediately followed the accident; that it did not exist prior to the accident for which compensation is claimed, and that it was accompanied by pain. The employee had been in the employ of the defendant company as a dispenser in one of its dye rooms continuously from February 1937 until July 14, 1937, the date he claimed to have suffered his injury. The employee's duties included bringing drums of hydrosol, weighing between 500 and 600 pounds, from a storeroom upstairs, inserting a spigot in the head of the drum and placing the drum on a low wooden rack. On the date of the accident, the employee, assisted by a fellow employee, was engaged in lifting a full drum of hydrosol on to the wooden rack when the spigot in the head of the drum became entangled with the framework of the rack and the drum slipped, jerking the employee and throwing a heavy strain on him for two or three minutes. With the assistance of a third employee, the drum was finally, after about ten minutes, placed in position. The employee continued working at lighter tasks for the remainder of that day. He stated that he was not conscious of any pain during the struggle with the metal drum, but after the lifting was over he said he "felt a tired and let down sensation." The next morning, July 15, when he got out of bed, he experienced a sharp pain, which continued that day and the following day, both of which days, however, he continued to work at light tasks. On July 17 he consulted a physician who diagnosed his trouble as inguinal hernia. On the succeeding morning he consulted the company physician, who made the same diagnosis and instructed him to quit work, which he did. The employee testified that he had no hernia or evidence of hernia previous to this accidental injury.

The employee had been operated on in the hernial region at the age of 7 years for an undescended testicle and was discharged as cured. The surgeon who performed this operation testified that there was no indication of hernia at that time. The company physician testified that the incision in the abdominal wall for the operation in question was at approximately the same place as for a hernia and that he found a scar in that region on the employee. He said with reference to that operation that it might or might not have caused a weakness of the tissues in that area and that a conclusion on that point could not be definitely stated. He testified, too, that the employee's hernia might have existed for several years but that there was

no way to determine from an examination when it had its inception or when the rupture occurred.

The industrial commission found that the hernia was congenital in origin and that it was caused by a preexisting weakness of the tissue. The Supreme Court, however, could find no evidence in the record to warrant that finding or a finding that the employee suffered from a hernia at any time prior to the accident. The commission found, too, that the employee felt no pain at the time of the accident, and the court thought that there was ample testimony in the record to support this finding. The employee repeatedly disclaimed that he felt pain at the time of the accident. He argued, however, that the language of the compensation act "that it was accompanied by pain," did not mean that pain must be coincident with the accidental injury, but that the appearance of the hernia must be accompanied by pain. As the court construed the act, however, the injury and the pain must be referable to a definite time, place and circumstance, and the pain must accompany the accidental injury. The court did not feel warranted in ascribing to the words "tired" and "exhausted" the common sense of the word "pain." Nontechnical definitions of "pain," said the court, while varying in form of expression, all connote some degree of present distress or suffering, contradistinguished from normal fatigue.

The court further thought that the words "suddenly" and "immediately" as used in the act in relation to hernia were elastic terms, admitting of much variety of definition. The court did not think that these words should be construed as the equivalent of the word instantaneous. Like other similar absolute expressions, they were used in the act with less strictness than the literal meaning requires. To give them their literal significance in all cases, regardless of the attendant situations and circumstances, would, the court said, often defeat meritorious claims on purely technical grounds.

Because, however, the employee felt no pain at the time of the accidental injury, the Supreme Court affirmed the judgment of the lower court disallowing the employee's claim for compensation.—*Rudd v. Fairforest Finishing Co. (S. C.)*, 200 S. E. 727.

Medical Services: Liability of County for Emergency Medical Services Rendered Indigents.—A physician, said the Supreme Court of Nebraska, not employed by a county may not recover from the county for services rendered to a poor person in an emergency when a county physician has been duly appointed to care for the poor, the latter physician being able, willing and ready to serve but not consulted. The ignorance of the attending physician of the fact that the county had regularly employed a county physician, and thus provided for the exclusive medical treatment of the poor, will avail him nothing.—*Miller v. Banner County (Neb.)*, 283 N. W. 206.

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Active Immunization Against Pertussis.—Between May 27, 1934, and July 30, 1935, Doull and his colleagues gave pertussis vaccine to 483 Cleveland children from 6 to 15 months of age. The vaccine was prepared from strains of *Haemophilus pertussis* recently isolated and proved to be in phase I of Leslie and Gardner. The children were selected from the active registers of five child welfare stations of the Cleveland Division of Health. As a control group 496 children comparable in age and other pertinent characteristics were selected from the same sources. Four inoculated children who contracted pertussis early in the study evidently received the first dose of vaccine while in the initial stages of the disease. These children were omitted from further study. For the whole period of 172 weeks of observation the number of cases of pertussis reported was seventy-four in the inoculated group and ninety-four in the control group. Although incidence somewhat favors the inoculated, the difference is not impressive. Seventy-five of the inoculated and sixty-two of the control group were exposed to pertussis by its being introduced into the family by an older child. In two of the former cases it was ascertained that the disease was probably present in the home at the time of the first inoculation. If these children are regarded as not inoculated at the time of exposure, there are seventy-three instances in which inoculated children were subjected to household exposure. Fifty-six, or 77 per cent, of the children were attacked. In the control group the sixty-two exposures resulted in sixty-one attacks. From these figures the most that can be concluded is that under conditions of household exposure the vaccine may have protected 23 per cent of the inoculated children from attack. In an endeavor to classify the cases according to severity the records of the cases have been studied by different persons, but every tabulation has demonstrated a higher proportion of mild attacks in the inoculated than in the control group. On the average, higher leukocyte counts were found for patients of the control than for those of the inoculated group. This fact may

be interpreted as indicating more severe systemic reactions in the former. However, no significant differences were observed in the lymphocyte counts.

Basal Metabolism in Osseous Tuberculosis.—Topper determined the basal metabolic rates of fifty children with tuberculosis of bone both in the frankly active and in the apparently inactive stage. All these children were afebrile at the time of study and for long periods before and after study. Some of them have been followed for one and two years. The purpose of the investigation was to determine whether the basal metabolism could be used in the diagnosis of the activity of osseous tuberculosis. Thirty-six had normal basal metabolic rates, irrespective of whether the lesion was frankly active or apparently inactive. In this group the sedimentation rate of the erythrocytes did not parallel the metabolism. In fact, even in cases in which there was low grade fever (temperatures up to 100 or 101 F.) the metabolism was not increased. Similarly, in ten cases in which there were actively draining sinuses the metabolism was normal. The metabolism of fourteen children was found to be increased. Since the temperature of these children was for the most part normal and the osseous lesions similar to those of the thirty-six children with normal metabolism, further analysis was made to determine the cause for the increased metabolism. Of these fourteen children, all except two had active pulmonary tuberculosis of the primary type. This is consistent with previous observations of increased metabolism in pulmonary tuberculosis. Serial studies in some of these cases showed that when the tuberculous process in the lungs became inactive the metabolism returned to a normal level, irrespective of whether the osseous lesion was active or inactive. Therefore, for the diagnosis of activity in osseous tuberculosis one must depend on the roentgenogram, the leukocyte count, the sedimentation rate and clinical signs and symptoms of activity. The cause for increased metabolism in the childhood type of pulmonary tuberculosis as opposed to normal metabolism in other types of the infection is probably related to the extensive involvement of lymphatic tissue in this type of tuberculosis. The oxygen consumption of lymphatic tissue has been shown to be high, and it is especially so when the functional activity of such tissue is increased.

Iron Deficiency Anemia in Children.—According to Abbott and Ahmann, a study of hemoglobin values of 883 rural school children in Florida showed that 50 per cent of them were anemic and that 31 per cent had borderline anemia. The ratio between the number of children with the highest and the number with the lowest hemoglobin values was approximately 1 to 5. The administration of iron and ammonium citrates to 200 rural school children over forty-two days resulted in a rapid regeneration of hemoglobin. A diet high in iron-carrying foods produced an increase in hemoglobin in the forty-seven nursery school children so treated, but in cases of severe anemia, even after ninety days of the diet, the hemoglobin values remained subnormal.

Estrogenic and Gonadotropic Hormones in Pregnant Women.—Rakoff studied a simplified improved technic for the titration of estrogenic and gonadotropic hormones in the serum of pregnant women, which proved to be useful in following the concentrations of these hormones in normal gestation and in a number of the complications of pregnancy, especially the toxemias and abortion. The method requires from 20 to 50 cc. of blood. Estrogenic hormone was assayed by a modification of the Fluhmann technic. Gonadotropic hormone was titrated by a modification of the Aschheim-Zondek test. Whole serums were used as the test solutions and mice as the test animals. It was observed that the estrogen and gonadotropic hormone values on unextracted serums are much higher than those obtained on extracted specimens. Serum titrations repeated at frequent intervals gave much more consistent results than those obtained from urinary assays. A total of 162 serum titrations were conducted on forty normal pregnant women in various periods of gestation, and graphs were prepared showing the normal range and average values from the fourth week of gestation to term. Serum titrations conducted on a group of twenty-two patients with toxemias of late pregnancy usually showed abnormally high gonadotropic hormone and low estrogen values. The severity of the toxemia did not appear to be directly related to the degree of abnormality in gonadotropic hormone and estrogen values, except that those patients with marked edema showed unusually high gonadotropic hormone readings in the serum. Improvement in the clinical condition was generally associated with a return of the estrogen and gonadotropic hormone values to the normal range. Studies on three patients in whom titrations were available before the onset of toxemia showed in two instances high gonadotropic hormone values preceding the onset of toxemia by several weeks. These were later followed by low estrogen values. There was gener-

ally a reciprocal relationship between the rise and fall of estrogen and gonadotropic hormone. Three patients with nephritic toxemia showed high gonadotropic hormone and usually low estrogen values during the period of clinical toxemia. However, one patient with a glomerulonephritis, who had a history of nephritic toxemia and eclampsia in the previous pregnancy, showed normal values for estrogen and gonadotropic hormones, except during two periods associated with signs and symptoms of toxemia. When intra-uterine fetal death was suspected, repeated examinations of the serum for gonadotropic hormone furnished a better means of determining the fate of the fetus than did the Friedman test. With the author's technic the gonadotropic hormone content of the serum fell to 50 m units per hundred cubic centimeters or less the Friedman usually became negative. One patient with pernicious nausea and vomiting had a low gonadotropic hormone content of serum, while the serum estrogen was normal.

Complications from Excessive Development of Fetus.—Koff and Potter say that, provided the pelvis is not contracted it is rare for infants weighing less than 4,500 Gm. to give to dystocia due to size. It has been found, however, that delivery of an infant weighing more than 4,500 Gm. is frequently attended with serious difficulties. Investigating the incidence of the birth of excessively developed fetuses, the authors found that among 20,219 births at the Chicago Lying-in Hospital 195, or 0.94 per cent, of the infants weighed more than 4,500 Gm. Since the size of the fetus is largely dependent the length of gestation, the authors investigated the duration of pregnancy (calculated from the first day of the last menstrual period) in the cases on which this study is based. The average length of gestation of the women with excessively developed fetuses was 288 days. This figure when compared with the figures for normal pregnancy demonstrates the direct relationship between prolongation of pregnancy and excessive development of the fetus. However, size of the parents, multiparity, advancing age, or diabetes in the mother may be contributory factors in producing excessive fetal development. Labor presents a greater hazard for both mother and offspring when overdevelopment of the fetus has occurred. The necessity for operative intervention is increased and the incidence of toxemia of postpartum hemorrhage, of maternal morbidity and of fetal mortality is definitely higher than when the fetus is small. Accurate estimation of fetal size prior to delivery with consequent modification of the technic employed will decrease maternal complications and fetal mortality.

Bacillus Welchii Infections in Pregnancy.—Russell and Roach report their experiences in seventeen cases of Bacillus welchii infections occurring in their clinic. They differentiate the following types: (1) local gas gangrene, (2) emphysema of the uterine wall and (3) gas sepsis. They subdivide the latter type into (a) general sepsis and (b) metastatic gas gangrene. After discussing these various types they give their attention to the differential diagnosis, pointing out that the physical examination does not give much information in Bacillus welchii infections because the predominating symptom is tenderness of the lower part of the abdomen, uterus, liver, kidneys and spleen and all these may be tender in a simple case of abortion. The heart cycle and pulse rate are again of no value. Peritonitis is not found in the mild cases, but it is found in cases in which there is a general sepsis with or without emphysema and phlegmon. Cyanosis is one of the common symptoms which accompany Bacillus welchii infection but it is important to differentiate between that resulting from sulfanilamide therapy or that which is seen in the later stages of eclampsia. Jaundice is another symptom which occurs in the more severe cases but not in those which are classified as local infection. The odor of the patient suffering from a Bacillus welchii infection is not much different from that associated with typhoid. The pulse also is similar; however, the patient suffering from the Bacillus welchii infection has not the facies of anxiety found in the patient with typhoid. The temperature is usually lower in the former disease than in the latter, and the patient suffering from a Bacillus welchii infection has a cold and clammy skin in contrast to the hot and moist skin of the typhoid patient. Incontinence of urine and feces is a rather common occurrence in severe infections of Bacillus welchii. The exact diagnosis is

Bacillus welchii infection is not always easy. Laboratory observations and x-ray examination are the final criteria for the diagnosis. The treatment of this infection is varied and there is no preparation which will cure all cases. Massive doses of a polyvalent serum for streptococci and *Bacillus welchii* should be administered on admission. Strict isolation of the patient is of great importance. Because of the spore-bearing properties of *Bacillus welchii*, the authors insist that all instruments and materials be fractionally sterilized. Repeated intra-uterine cultures, douches and transfusions should be made as soon as the organism has been identified by smears and cultures. It is important also to combat acidosis, anemia and low urinary output. The senior author decided that hydrogen peroxide and a gentle débridement of the necrotic materials; the liberated oxygen would destroy the anaerobes, and the dibrom-oxymery-fluorescein would destroy those organisms causing the mixed infection found in the more severe cases. He suggests that these intra-uterine douches be repeated at least every other day because of the spore-bearing characteristics of *Bacillus welchii*. Vaginal instillations with the same mixture seemed to be efficacious in the treatment of the vaginal necrosis and were given twice daily. The authors emphasize that gas producing bacteria should be of extreme importance to doctors in contact with rural patients because these bacteria are often found in the intestinal tract of herbivorous animals.

Fever Therapy in Acute Rheumatic Disease.—The effects of physically induced fever in thirty-one cases of acute rheumatic fever in which the Kettering hypertherm cabinet was used are reported by Simmons and Dunn. The patients have been under observation for from one month to three and one half years. In the group there were eleven cases of mitral stenosis, fourteen of systolic murmurs, one of acute pericarditis, one of pericarditis and effusion and one of acute carditis and a pulse deficit. Complete and prompt relief of joint pain and swelling was obtained in almost all cases. The periods of artificial fever (from 103 to 106 F.) varied from five to sixty-five hours. In no case was it possible to determine that the cardiac lesions were aggravated by fever therapy. The period of subclinical activity was shortened and in the cases of minimal cardiac involvement the murmurs disappeared. These results cannot be fully ascribed to the effect of fever therapy alone. Symptomatic relief from joint pain has been afforded regardless of the presence of significant foci of infection, but data on the prolonged effect of fever therapy on such foci are not had since they were removed subsequently. Fever therapy is not a substitute for the removal of significant foci of infection. Fifteen of twenty cases showed a sharp drop in the sedimentation rate during the course of or immediately following fever therapy. More time must elapse and larger groups must be observed before the position of fever therapy can be established, but the authors feel that it is of definite aid in the treatment of acute rheumatic fever.

Desoxycorticosterone Acetate for Addison's Disease.

To date Cleghorn and his colleagues have used desoxycorticosterone acetate in nine cases of Addison's disease and in all there has been undoubted clinical improvement. The principal subjective benefit appears to be a greatly increased sense of well being and vigor. Objectively the blood pressure, serum sodium and body weight increase. Hemoconcentration disappears, as indicated by the fall in hemoglobin and the decrease in the percentage of erythrocytes. Added salt is tolerated better and the appetite improves. Desoxycorticosterone acetate has a definite advantage in that it can be given in small injections and is less painful than adrenal cortex extract. Cases of local reaction with fever following the use of desoxycorticosterone acetate in oil have been reported, but the authors believe that this is due to accidental subcutaneous injection. It must be injected intramuscularly. The danger of using the test recently described by Cutler, Power and Wilder (the withholding of salt) as being diagnostic for Addison's disease is emphasized.

Electro-Encephalography.—According to Hyland and his associates, the principal clinical value of the electro-encephalogram in its present stage of development, apart from the study of epilepsy, is in the localization of tumors which involve the cerebral cortex. In other organic diseases of the brain and in mental disorders the usefulness of the electro-encephalogram is still limited. Gross abnormalities in the recorded waves are usually absent in the majority of these conditions. Further repeated investigation is necessary, particularly in cases in which the otherwise normal "alpha" frequency is found to be below 7½ per second or less, may be seen alone or in conjunction with other slow waves. While little is known regarding their significance, there is some evidence to indicate that they represent pathologic changes associated with an impairment of cortical function. Here again future investigations doubtless will result in improved methods of recording and in the interpretation of observations, so that the scope of the electro-encephalogram in diagnosis may be greatly increased.

Self Selection of Diets by Children.—Over a period of six years Davis observed the results on fifteen infants from the time of weaning (from 6 to 11 months of age) on a self selected diet. Each child was observed for not less than six months and all but two from one to four and a half years. Food was not offered to the infant either directly or by suggestion. The nurses' orders were to sit quietly by, spoon in hand, and make no motion, and only when the infant reached for or pointed to a dish might she take up a spoonful and, if he opened his mouth for it, put it in. He might eat with

his fingers or in any way he could without comment on or correction of his manners. The tray was taken away when he had definitely stopped eating, which was usually after from twenty to twenty-five minutes. The foods offered were weighed before and after the infant's selection. There were no failures of infants to manage their own diets; all had hearty appetites; all thrived. Constipation was unknown among them and laxatives were never used or needed. Except in the presence of parenteral infection, there was no vomiting or diarrhea. Colds were usually of the mild three day type without complications of any kind. There were a few cases of tonsillitis but no serious illness among the children in the six years. The only epidemic disease to visit the nursery was acute glandular fever of Pfeiffer, with which all the children in the nursery came down like ninepins on the same day. During this epidemic trays were served as usual. This led to the observation that, just as loss of appetite often precedes by twenty-four to forty-eight hours every other discoverable sign and symptom of acute infection, so return of appetite precedes by twelve to twenty-four hours all other signs of convalescence, occurring when fever is still high and enabling the observer to predict its fall correctly. This eating of a hearty meal when fever is still high is often not in evidence when children are put on restricted diets during such illnesses. The correctness of the observation has been confirmed in the Children's Memorial Hospital, where a modification of the self-selective method of feeding prevails. During convalescence unusually large amounts of raw beef, carrots and beets were eaten. The demand for increased amounts of raw beef and carrots can be easily accounted for but for the beets; it may be possible that they furnish an antianemic substance (iron?). Beets were eaten by all in much larger quantities in the first six months or year after weaning than ever again save after colds and acute glandular fever. Whether appetite was or was not a competent guide to an adequate diet was checked by diets with nutritional laws and standards and it was found that the infants either approximated or exceeded the average daily calory requirement. There was a moderate preponderance of the potentially alkaline in every six months period in fourteen infants. The other one was observed for only six months. The food list was confined to natural, unprocessed and unpurified foods, without made dishes of any sort, and it reproduced to a large extent the conditions under which primitive peoples in many parts of the world have been shown to have had scientifically sound diets and excellent nutrition. By providing conditions under which appetite could function freely and beneficently the experiment resolved the modern conflict between appetite and nutritional requirements. It eliminated anorexia and the eating problems that are the plague of feeding by the dosage method.

Bacteria Obtained from Mouth.—By the use of anaerobic methods and of a wide variety of culture mediums, Bibby and Berry isolated from the mouth many strains of filamentous bacteria. On the basis of the morphology and the characteristics of growth of the eighty-three strains which were successfully carried in subculture, a tentative working division into seven groups is proposed. Six of these have distinct characteristics. Only two, however, can be identified with organisms which have been isolated by previous investigators, although organisms showing some resemblance to a third group have been described. Four of the groups of filaments have the characteristics of the genus *Leptotrichia*, one of the genus *Fusiformis* and one of both genera. Of all the groups, only one embraced strains all of which were alike in biologic properties. For these organisms the authors suggest the name *Leptotrichia buccalis* because they represent the most commonly isolated of the culturable oral filaments.
